# Programming interface to the

# **Swiss Ephemeris**

#### Copyright Astrodienst AG 1997-2019.

This document describes the proprietary programmer's interface to the Swiss Ephemeris library.

The Swiss Ephemeris is made available by its authors under a dual licensing system. The software developer, who uses any part of Swiss Ephemeris in his or her software, must choose between one of the two license models, which are:

- a) GNU public license version 2 or later;
- b) Swiss Ephemeris Professional License.

The choice must be made before the software developer distributes software containing parts of Swiss Ephemeris to others, and before any public service using the developed software is activated.

If the developer chooses the GNU GPL software license, he or she must fulfill the conditions of that license, which includes the obligation to place his or her whole software project under the GNU GPL or a compatible license. See

• http://www.gnu.org/licenses/old-licenses/gpl-2.0.html.

If the developer chooses the Swiss Ephemeris Professional license, he must follow the instructions as found in

http://www.astro.com/swisseph/

and purchase the Swiss Ephemeris Professional Edition from Astrodienst and sign the corresponding license contract.

# 1. The programming steps to get a planet's position

To compute a celestial body or point with SWISSEPH, you have to do the following steps (use swetest.c as an example). The details of the functions will be explained in the following chapters.

```
1. Set the directory path of the ephemeris files, e.g.:
```

```
swe_set_ephe_path("C:\\SWEPH\\EPHE");
```

2. From the birth date, compute the Julian day number:

```
jul_day_UT = swe_julday(year, month, day, hour, gregflag);
```

3. Compute a planet or other bodies:

```
ret_flag = swe_calc_ut(jul_day_UT, planet_no, flag, lon_lat_rad, err_msg);
or a fixed star:
    ret_flag = swe_fixstar_ut(star_nam, jul_day_UT, flag, lon_lat_rad, err_msg);
```

#### NOTE:

The functions swe\_calc\_ut() and swe\_fixstar\_ut() were introduced with Swisseph version 1.60.

If you use a Swisseph version older than 1.60 or if you want to work with Ephemeris Time, you have to proceed as follows instead:

first, if necessary, convert universal time (UT) to ephemeris time (ET):

```
jul_day_ET = jul_day_UT + swe_deltat(jul_day_UT);
```

then compute a planet or other bodies:

```
ret_flag = swe_calc(jul_day_ET, planet_no, flag, lon_lat_rad, err_msg);
```

or a fixed star:

```
ret_flag = swe_fixstar(star_nam, jul_day_ET, flag, lon_lat_rad, err_msg);
```

4. At the end of your computations close all files and free memory calling swe\_close();

Here is a miniature sample program, it is in the source distribution as swemini.c:

```
#include "swephexp.h"
                          /* this includes "sweodef.h" */
int main()
char *sp, sdate[AS MAXCH], snam[40], serr[AS MAXCH];
int jday = 1, jmon = 1, jyear = 2000;
double jut = 0.0;
double tjd_ut, te, x2[6];
long iflag, iflgret;
int p;
swe_set_ephe_path(NULL);
iflag = SEFLG SPEED;
while (TRUE) {
printf("\nDate (d.m.y) ?");
gets(sdate);
     /* stop if a period . is entered */
if (*sdate == '.')
return OK;
if (sscanf (sdate, "%d%*c%d"*c%d", &jday, &jmon, &jyear) < 1) exit(1);</pre>
     /*
     * we have day, month and year and convert to Julian day number
tjd_ut = swe_julday(jyear, jmon, jday, jut, SE_GREG_CAL);
     * compute Ephemeris time from Universal time by adding delta t
     * not required for Swisseph versions smaller than 1.60
```

swephprg.doc ~1~

```
*/
/* te = tjd ut + swe deltat(tjd ut); */
printf("date: %02d.%02d.%d at 0:00 Universal time\n", jday, jmon, jyear);
printf("planet \tlongitude\tlatitude\tdistance\tspeed long.\n");
     * a loop over all planets
     */
for (p = SE_SUN; p <= SE_CHIRON; p++) {</pre>
if (p == SE EARTH) continue;
     * do the coordinate calculation for this planet p
     */
iflgret = swe_calc_ut(tjd_ut, p, iflag, x2, serr);
/* Swisseph versions older than 1.60 require the following
* statement instead */
/* iflgret = swe_calc(te, p, iflag, x2, serr); */
     /* if there is a problem, a negative value is returned and an
     * error message is in serr.
     */
if (iflgret < 0)
     printf("error: %s\n", serr);
     * get the name of the planet p
swe_get_planet_name(p, snam);
     * print the coordinates
printf("%10s\t%11.7f\t%10.7f\t%10.7f\t%10.7f\n",
     snam, x2[0], x2[1], x2[2], x2[3]);
}
}
return OK;
```

# 2. The Ephemeris file related functions

# 2.1. swe\_set\_ephe\_path()

This is the first function that should be called before any other function of the Swiss Ephemeris. Even if you don't want to set an ephemeris path and use the Moshier ephemeris, it is nevertheless recommended to call swe\_set\_ephe\_path(NULL), because this function makes important initializations. If you don't do that, the Swiss Ephemeris may work, but the results may be not 100% consistent.

If the environment variable SE\_EPHE\_PATH exists in the environment where Swiss Ephemeris is used, its content is used to find the ephemeris files. The variable can contain a directory name, or a list of directory names separated by ; (semicolon) on Windows or : (colon) on Unix.

```
void swe_set_ephe_path(
     char *path);
```

Usually an application will want to set its own ephemeris, e.g. as follows:

```
swe_set_ephe_path("C:\\SWEPH\\EPHE");
```

The argument can be a single directory name or a list of directories, which are then searched in sequence. The argument of this call is ignored if the environment variable SE EPHE PATH exists and is not empty.

swephprg.doc ~ 2 ~

If you want to make sure that your program overrides any environment variable setting, you can use **putenv()** to set it to an empty string.

If the path is longer than 256 bytes, swe\_set\_ephe\_path() sets the path \SWEPH\EPHE instead.

If no environment variable exists and swe\_set\_ephe\_path() is never called, the built-in ephemeris path is used. On Windows it is "\sweph\ephe" relative to the current working drive, on Unix it is "\users\ephe".

Asteroid ephemerides are looked for in the subdirectories ast0, ast1, ast2 .. ast9 of the ephemeris directory and, if not found there, in the ephemeris directory itself. Asteroids with numbers 0 - 999 are expected in directory ast0, those with numbers 1000 - 1999 in directory ast1 etc.

The environment variable SE\_EPHE\_PATH is most convenient when a user has several applications installed which all use the Swiss Ephemeris but would normally expect the ephemeris files in different application-specific directories. The use can override this by setting the environment variable, which forces all the different applications to use the same ephemeris directory. This allows him to use only one set of installed ephemeris files for all different applications. A developer should accept this override feature and allow the sophisticated users to exploit it.

#### 2.2. swe close()

```
/* close Swiss Ephemeris */
void swe_close(
    void);
```

At the end of your computations you can release all resources (open files and allocated memory) used by the Swiss Ephemeris DLL.

After swe\_close(), no Swiss Ephemeris functions should be used unless you call swe\_set\_ephe\_path() again and, if required, swe\_set\_jpl\_file().

# 2.3. swe\_set\_jpl\_file()

If you work with the JPL ephemeris, SwissEph uses the default file name which is defined in swephexp.h as SE\_FNAME\_DFT. Currently, it has the value "de406.eph" or "de431.eph".

If a different JPL ephemeris file is required, call the function **swe\_set\_jpl\_file()** to make the file name known to the software, e.g.

```
swe_set_jpl_file("de405.eph");
```

This file must reside in the ephemeris path you are using for all your ephemeris files.

If the file name is longer than 256 byte, swe\_set\_jpl\_file() cuts the file name to a length of 256 bytes. The error will become visible after the first call of swe\_calc(), when it will return zero positions and an error message.

#### 2.4. swe\_version()

The function returns a pointer to the string svers, i.e. to the version number of the Swiss Ephemeris that your software is using.

# 2.5. swe\_get\_library\_path()

swephprg.doc ~ 3 ~

The function returns a pointer to the string spath, which contains the path in which the executable resides. If it is running with a DLL, then spath contains the path of the DLL.

# 3. The functions swe\_calc\_ut() and swe\_calc()

Before calling one of these functions or any other Swiss Ephemeris function, it is strongly recommended to call the function swe\_set\_ephe\_path(). Even if you don't want to set an ephemeris path and use the Moshier ephemeris, it is nevertheless recommended to call swe\_set\_ephe\_path(NULL), because this function makes important initializations. If you don't do that, the Swiss Ephemeris may work but the results may be not 100% consistent.

#### 3.1. The call parameters

swe\_calc\_ut() was introduced with Swisseph version 1.60 and makes planetary calculations a bit simpler. For the steps required, see the chapter The programming steps to get a planet's position.

swe\_calc\_ut() and swe\_calc() work exactly the same way except that swe\_calc() requires Ephemeris Time (more accurate: Dynamical Time) as a parameter whereas swe\_calc\_ut() expects Universal Time. For common astrological calculations, you will only need swe\_calc\_ut() and will not have to think any more about the conversion between Universal Time and Ephemeris Time.

swe\_calc\_ut() and swe\_calc() compute positions of planets, asteroids, lunar nodes and apogees. They are defined
as follows:

```
int swe_calc_ut(
      double tjd ut,
      int ipl,
      int iflag,
      double* xx,
      char* serr);
where
          = Julian day, Universal Time
tjd ut
          = body number
ipl
          = a 32 bit integer containing bit flags that indicate what kind of computation is wanted
iflag
          = array of 6 doubles for longitude, latitude, distance, speed in long., speed in lat., and speed in dist.
serr[256] = character string to return error messages in case of error.
and
int swe_calc(
      double tid et,
      int ipl,
      int iflag,
      double *xx,
      char *serr);
same but
          = Julian day, Ephemeris time, where tjd_et = tjd_ut + swe_deltat(tjd_ut)
A detailed description of these variables will be given in the following sections.
```

#### 3.2. Bodies (int ipl)

To tell swe\_calc() which celestial body or factor should be computed, a fixed set of body numbers is used. The body numbers are defined in swephexp.h:

swephprg.doc ~ 4 ~

```
#define SE_MERCURY
                                   2
#define SE_VENUS
                                   3
#define SE MARS
                                   4
#define SE_JUPITER
                                   5

```

#### 3.2.1. Additional asteroids

```
Body numbers of other asteroids are above SE_AST_OFFSET (= 10000) and have to be constructed as follows:

ipl = SE_AST_OFFSET + minor_planet_catalogue_number;

e.g. Eros : ipl = SE_AST_OFFSET + 433
```

The names of the asteroids and their catalogue numbers can be found in seasnam.txt.

Examples are:

5 Astraea

6	Hebe	
7	Iris	
8	Flora	
9	Metis	
10	Hygiea	
30	Urania	
42	Isis	not identical with "Isis-Transpluto"
153	Hilda	has an own asteroid belt at 4 AU
227	Philosophia	
251	Sophia	
259	Aletheia	
275	Sapientia	
279	Thule	asteroid close to Jupiter
375	Ursula	
433	Eros	
763	Cupido	different from Witte's Cupido
944	Hidalgo	
1181	Lilith	not identical with Dark Moon 'Lilith'
1221	Amor	
1387	Kama	
1388	Aphrodite	
1862	Apollo	different from Witte's Apollon
3553	Damocles	highly eccentric orbit between Mars and Uranus
3753	Cruithne	"second moon" of Earth
4341	Poseidon	Greek Neptune - different from Witte's Poseidon
4464	Vulcano	fire god - different from Witte's Vulkanus and intramercurian Vulcan
5731	Zeus	Greek Jupiter - different from Witte's Zeus
7066	Nessus	third named Centaur - between Saturn and Pluto
There a	are two ephem	eris files for each asteroid (except the main asteroids), a long one and a short o

se09999.se1 long-term ephemeris of asteroid number 9999, 3000 BC - 3000 AD

se09999s.se1 short ephemeris of asteroid number 9999, 1500 - 2100 AD

The larger file is about 10 times the size of the short ephemeris. If the user does not want an ephemeris for the time before 1500 he might prefer to work with the short files. If so, just copy the files ending with "s.se1" to your hard disk. swe\_calc() tries the long one and on failure automatically takes the short one.

Asteroid ephemerides are looked for in the subdirectories ast0, ast1, ast2 .. ast9 etc. of the ephemeris directory and, if not found there, in the ephemeris directory itself. Asteroids with numbers 0 - 999 are expected in directory ast0, those with numbers 1000 - 1999 in directory ast1 etc.

Note that not all asteroids can be computed for the whole period of Swiss Ephemeris. The orbits of some of them are extremely sensitive to perturbations by major planets. E.g. CHIRON, cannot be computed for the time before 650 AD and after 4650 AD because of close encounters with Saturn. Outside this time range, Swiss Ephemeris returns the error code, an error message, and a position value 0. Be aware, that the user will have to handle this case in his program. Computing Chiron transits for Jesus or Alexander the Great will not work.

The same is true for Pholus before 3850 BC, and for many other asteroids, as e.g. 1862 Apollo. He becomes chaotic before the year 1870 AD, when he approaches Venus very closely. Swiss Ephemeris does not provide positions of Apollo for earlier centuries!

#### **NOTE** on asteroid names:

Asteroid names are listed in the file seasnam.txt. This file is in the ephemeris directory.

~6~ swephprg.doc

#### 3.2.2. Fictitious planets

Fictitious planets have numbers greater than or equal to 40. The user can define his or her own fictitious planets. The orbital elements of these planets must be written into the file seorbel.txt. The function swe\_calc() looks for the file seorbel.txt in the ephemeris path set by swe\_set\_ephe\_path(). If no orbital elements file is found, swe\_calc() uses the built-in orbital elements of the above mentioned Uranian planets and some other bodies. The planet number of a fictitious planet is defined as

```
ipl = SE_FICT_OFFSET_1 + number_of_elements_set;
e.g. for Kronos: ip1 = 39 + 4 = 43.
The file seorbel.txt has the following structure:
# Orbital elements of fictitious planets
# 27 Jan. 2000
 This file is part of the Swiss Ephemeris, from Version 1.60 on.
#
# Warning! These planets do not exist!
# The user can add his or her own elements.
 960 is the maximum number of fictitious planets.
# The elements order is as follows:
# 1. epoch of elements (Julian day)
# 2. equinox (Julian day or "J1900" or "B1950" or "J2000" or "JDATE")
# 3. mean anomaly at epoch
# 4. semi-axis
# 5. eccentricity
# 6. argument of perihelion (ang. distance of perihelion from node)
# 7. ascending node
# 8. inclination
# 9. name of planet
# use '#' for comments
# to compute a body with swe_calc(), use planet number
# ipl = SE FICT OFFSET 1 + number of elements set,
\# e.g. number of Kronos is ipl = 39 + 4 = 43

All orbital elements except epoch and equinox may have T terms, where:
T = (tid - epoch) / 36525.
```

(See, e.g., Vulcan, the second last elements set (not the "Uranian" Vulcanus but the intramercurian hypothetical planet Vulcan).) "T \* T", "T2", "T3" are also allowed.

The equinox can either be entered as a Julian day or as "J1900" or "B1950" or "J2000" or, if the equinox of date is required, as "JDATE". If you use T terms, note that precession has to be taken into account with JDATE, whereas it has to be neglected with fixed equinoxes.

No T term is required with the mean anomaly, i.e. for the speed of the body, because our software can compute it from semi-axis and gravity. However, a mean anomaly T term had to be added with Vulcan because its speed is not in agreement with the laws of physics. In such cases, the software takes the speed given in the elements and does not compute it internally.

From Version 1.62 on, the software also accepts orbital elements for fictitious bodies that move about the Earth. As an example, study the last elements set in the excerpt of seorbel.txt above. After the name of the body, ", geo" has to be added.

#### 3.2.3. Obliquity and nutation

A special body number SE\_ECL\_NUT is provided to compute the obliquity of the ecliptic and the nutation. Of course nutation is already added internally to the planetary coordinates by swe\_calc() but sometimes it will be needed as a separate value.

```
iflgret = swe_calc(tjd_et, SE_ECL_NUT, 0, x, serr);
x is an array of 6 doubles as usual. They will be filled as follows:
x[0] = true obliquity of the Ecliptic (includes nutation)
x[1] = mean obliquity of the Ecliptic
x[2] = nutation in longitude
x[3] = nutation in obliquity
x[4] = x[5] = 0
```

# 3.3. Options chosen by flag bits (long iflag)

#### 3.3.1. The use of flag bits

If no bits are set, i.e. if iflag == 0, swe\_calc() computes what common astrological ephemerides (as available in book shops) supply, i.e. an <u>apparent</u> body position in **geocentric** ecliptic polar coordinates (longitude, latitude, and distance) relative to the true <u>equinox of the date</u>.

If the speed of the body is required, set iflag = SEFLG\_SPEED.

For mathematical points as the mean lunar node and the mean apogee, there is no apparent position. swe calc()

swephprg.doc ~ 8 ~

returns true positions for these points.

If you need another kind of computation, use the flags explained in the following paragraphs (c.f. swephexp.h). Their names begin with ,SEFLG\_f. To combine them, you have to concatenate them (inclusive-or) as in the following example:

```
iflag = SEFLG SPEED | SEFLG TRUEPOS; (or: iflag = SEFLG SPEED + SEFLG TRUEPOS;) // C
iflag = SEFLG SPEED or SEFLG TRUEPOS; (or: iflag = SEFLG SPEED + SEFLG TRUEPOS;) // Pascal
```

With this value of iflag, swe\_calc() will compute true positions (i.e. not accounted for light-time) with speed.

The flag bits, which are defined in swephexp.h, are:

```
#define SEFLG JPLEPH
                           1L
                                             // use JPL ephemeris
#define SEFLG SWIEPH
                           2L
                                             // use SWISSEPH ephemeris, default
#define SEFLG MOSEPH
                           4L

```

#### 3.3.2. **Ephemeris flags**

The flags to choose an ephemeris are: (s. swephexp.h)

```
SEFLG_JPLEPH /* use JPL ephemeris */
SEFLG SWIEPH /* use Swiss Ephemeris */
SEFLG_MOSEPH /* use Moshier ephemeris */
```

If none of this flags is specified, swe calc() tries to compute the default ephemeris. The default ephemeris is defined in swephexp.h:

```
#define SEFLG DEFAULTEPH SEFLG SWIEPH
```

In this case the default ephemeris is Swiss Ephemeris. If you have not specified an ephemeris in iflag, swe calc() tries to compute a Swiss Ephemeris position. If it does not find the required Swiss Ephemeris file either, it computes a Moshier position.

#### 3.3.3. Speed flag

Swe\_calc() does not compute speed if you do not add the speed flag SEFLG\_SPEED. E.g. iflag |= SEFLG\_SPEED;

The computation of speed is usually cheap, so you may set this bit by default even if you do not need the speed.

~ 9 ~

#### 3.3.4. Coordinate systems, degrees and radians

SEFLG EQUATORIAL returns equatorial positions: right ascension and declination.

SEFLG XYZ returns x, y, z coordinates instead of longitude, latitude, and distance.

SEFLG\_RADIANS returns position in radians, not degrees.

E.g. to compute right ascension and declination, write:

iflag = SEFLG\_SWIEPH | SEFLG\_SPEED | SEFLG\_EQUATORIAL;

**NOTE** concerning equatorial coordinates: With sidereal modes SE\_SIDM\_J2000, SE\_SIDM\_B1950, SE\_SIDM\_J1900, SE\_SIDM\_GALALIGN\_MARDYKS or if the sidereal flag SE\_SIDBIT\_ECL\_T0 is set, the function provides right ascension and declination relative to the mean equinox of the reference epoch (J2000, B1950, J1900, etc.).

With other sidereal modes or ayanamshas right ascension and declination are given relative to the mean equinox of date.

#### 3.3.5. Specialties (going beyond common interest)

#### 5.1. True or apparent positions

Common ephemerides supply apparent geocentric positions. Since the journey of the light from a planet to the Earth takes some time, the planets are never seen where they actually are, but where they were a few minutes or hours before. Astrology uses to work with the positions **we see**. (More precisely: with the positions we would see, if we stood at the center of the Earth and could see the sky. Actually, the geographical position of the observer could be of importance as well and topocentric positions could be computed, but this is usually not taken into account in astrology.). The geocentric position for the Earth (SE\_EARTH) is returned as zero.

To compute the **true** geometrical position of a planet, disregarding light-time, you have to add the flag SEFLG\_TRUEPOS.

#### 5.2. Topocentric positions

To compute topocentric positions, i.e. positions referred to the place of the observer (the birth place) rather than to the center of the Earth, do as follows:

- call <a href="mailto:swe\_set\_topo">swe\_set\_topo</a> (geo\_lon, geo\_lat, altitude\_above\_sea) (The geographic longitude and latitude must be in degrees, the altitude in meters.)
- add the flag SEFLG TOPOCTR to iflag
- call swe\_calc(...)

#### 5.3. Heliocentric positions

To compute a heliocentric position, add SEFLG\_HELCTR.

A heliocentric position can be computed for all planets including the moon. For the sun, lunar nodes and lunar apogees the coordinates are returned as zero; **no error message appears**.

#### 5.4. Barycentric positions

SEFLG\_BARYCTR yields coordinates as referred to the solar system barycenter. However, this option is not completely implemented. It was used for program tests during development. It works only with the JPL and the Swiss Ephemeris, not with the Moshier ephemeris; and only with physical bodies, but not with the nodes and the apogees.

Moreover, the barycentric Sun of Swiss Ephemeris has "only" a precision of 0.1". Higher accuracy would have taken a lot of storage, on the other hand it is not needed for precise geocentric and heliocentric positions. For more precise barycentric positions the JPL ephemeris file should be used.

A barycentric position can be computed for all planets including the sun and moon. For the lunar nodes and lunar apogees the coordinates are returned as zero; no error message appears.

#### 5.5. Astrometric positions

For astrometric positions, which are sometimes given in the Astronomical Almanac, the light-time correction is computed, but annual aberration and the light-deflection by the sun neglected. This can be done with SEFLG\_NOABERR and SEFLG\_NOGDEFL. For positions related to the mean equinox of 2000, you must set SEFLG\_J2000 and SEFLG\_NONUT, as well.

#### 5.6. True or mean equinox of date

swe\_calc() usually computes the positions as referred to the true equinox of the date (i.e. with nutation). If you want

swephprg.doc ~ 10 ~

the mean equinox, you can turn nutation off, using the flag bit SEFLG NONUT.

#### 5.7. J2000 positions and positions referred to other equinoxes

swe\_calc() usually computes the positions as referred to the equinox of date. SEFLG\_J2000 yields data referred to the equinox J2000. For positions referred to other equinoxes, SEFLG\_SIDEREAL has to be set and the equinox specified by swe\_set\_sid\_mode(). For more information, read the description of this function.

#### 5.8. Sidereal positions

To compute sidereal positions, set bit SEFLG\_SIDEREAL and use the function swe\_set\_sid\_mode() in order to define the ayanamsha you want. For more information, read the description of this function.

#### 5.9. JPL Horizons positions

For apparent positions of the planets, JPL Horizons follows a different approach from Astronomical Almanac and from the IERS Conventions 2003 and 2010. It uses the old precession models IAU 1976 (Lieske) and nutation IAU 1980 (Wahr) and corrects the resulting positions by adding daily-measured celestial pole offsets (delta\_psi and delta\_epsilon) to nutation. (IERS Conventions 1996, p. 22) While this approach is more accurate in some respect, it is not referred to the same reference frame. For more details see the general documentation of the Swiss Ephemeris in swisseph.doc or <a href="http://www.astro.com/swisseph/swisseph.htm">http://www.astro.com/swisseph/swisseph.htm</a>, ch. 2.1.2.2.

Apparent positions of JPL Horizons can be reproduced with about 0.001 arcsec precision using the flag SEFLG\_JPLHOR. For best accuracy, the daily Earth orientation parameters (EOP) delta\_psi and delta\_eps relative to the IAU 1980 precession/nutation model must be downloaded and saved in the ephemeris path defined by swe\_set\_ephe\_path(). The EOP files are found on the IERS website:

http://www.iers.org/IERS/EN/DataProducts/EarthOrientationData/eop.html

The following files are required:

1. EOP 08 C04 (IAU1980) - one file (1962-now)

http://datacenter.iers.org/eop/-/somos/5Rqv/document/tx14iers.0z9/eopc04 08.62-now

Put this file into your ephemeris path and rename it as "eop\_1962\_today.txt".

2. finals.data (IAU1980)

http://datacenter.iers.org/eop/-/somos/5Rgv/document/tx14iers.0g0/finals.data

Put this file into your ephemeris path, too, and rename it as "eop\_finals.txt".

If the Swiss Ephemeris does not find these files, it defaults to SEFLG\_JPLHORA, which is a very good approximation of Horizons, at least for 1962 to present.

SEFLG JPLHORA can be used independently for the whole time range of the Swiss Ephemeris.

Note, the Horizons mode works only with planets and fixed stars. With lunar nodes and apsides, we use our standard methods.

# 3.4. Position and Speed (double xx[6])

swe calc() returns the coordinates of position and velocity in the following order:

Ecliptic position	Equatorial position (SEFLG_EQUATORIAL)
Longitude	right ascension
Latitude	declination
Distance in AU	distance in AU
Speed in longitude (deg/day)	speed in right ascension (deg/day)
Speed in latitude (deg/day)	speed in declination (deg/day)
Speed in distance (AU/day)	speed in distance (AU/day)

If you need rectangular coordinates (SEFLG\_XYZ), swe\_calc() returns x, y, z, dx, dy, dz in AU.

Once you have computed a planet, e.g., in ecliptic coordinates, its equatorial position or its rectangular coordinates are available, too. You can get them very cheaply (little CPU time used), calling again swe\_calc() with the same parameters, but adding SEFLG\_EQUATORIAL or SEFLG\_XYZ to iflag, swe\_calc() will not compute the body again, just return the data specified from internal storage.

swephprg.doc ~11 ~

#### 3.5. Error handling and return values

swe\_calc() (as well as swe\_calc\_ut(), swe\_fixstar(), and swe\_fixstar\_ut()) returns a 32-bit integer value. This
value is >= 0, if the function call was successful, and < 0, if a fatal error has occurred. In addition an error string or a
warning can be returned in the string parameter serr.</pre>

A fatal error code (< 0) and an error string are returned in one of the following cases:

- if an illegal <u>body number</u> has been specified;
- if a Julian day beyond the ephemeris limits has been specified;
- if the length of the ephemeris file is not correct (damaged file);
- on read error, e.g. a file index points to a position beyond file length (data on file are corrupt);
- if the copyright section in the ephemeris file has been destroyed.

If any of these errors occurs:

- the return code of the function is -1;
- the position and speed variables are set to zero;
- the type of error is indicated in the error string serr.

On success, the return code contains flag bits that indicate what kind of computation has been done. This value will usually be equal to iflag, however sometimes may differ from it. If an option specified by iflag cannot be fulfilled or makes no sense, swe\_calc just does what can be done. E.g., if you specify that you want JPL ephemeris, but swe\_calc cannot find the ephemeris file, it tries to do the computation with any available ephemeris. The ephemeris actually used will be indicated in the return value of swe\_calc. So, to make sure that swe\_calc() has found the ephemeris required, you may want to check, e.g.:

```
if (return_code > 0 && (return_code & SEFLG_JPLEPH))
```

However, usually it should be sufficient to do the ephemeris test once only, at the very beginning of the program.

In such cases, there is also a warning in the error string serr, saying that:

```
warning: SwissEph file 'sepl_18.se1' not found in PATH '...'; using Moshier eph.;
```

Apart from that, positive values of return\_code need not be checked, but maybe useful for debugging purposes or for understanding what exactly has been done by the function.

Some flags may be removed, if they are incompatible with other flags, e.g.:

- if two or more ephemerides (SEFLG\_JPLEPH, SEFLG\_SWIEPH, SEFLG\_MOSEPH) are combined.
- if the topocentric flag (SEFLG\_TOPOCTR) is combined with the heliocentric (SEFLG\_HELCTR) or the barycentric flag (SEFLG\_BARYCTR).
- etc.

Some flags may be added in the following cases:

- If no ephemeris flag was specified, the return value contains SEFLG SWIEPH;
- With J2000 calculations (SEFLG\_J2000) or other sidereal calculations (SEFLG\_SIDEREAL), the no-nutation flag (SEFLG\_NONUT) is added;
- With heliocentric (SEFLG\_HELCTR) and barycentric (SEFLG\_BARYCTR) calculations, the flags for "no aberration" (SEFLG\_NOABERR) and "no light deflection" (SEFLG\_NOGDEFL) are added.

# 4. The function swe\_get\_planet\_name()

This function allows to find a planetary or asteroid name, when the planet number is given. The function definition is:

```
char* swe_get_planet_name(
    int ipl,
    char *spname);
```

If an asteroid name is wanted, the function does the following:

- The name is first looked for in the asteroid file.
- Because many asteroids, especially the ones with high catalogue numbers, have no names yet (or have only a
  preliminary designation like 1968 HB), and because the Minor Planet Center of the IAU add new names quite often,
  it happens that there is no name in the asteroid file although the asteroid has already been given a name. For this,

swephprg.doc ~ 12 ~

Swiss Ephemeris 2.08 Fixed stars functions

we have the file seasnam.txt, a file that contains a list of all named asteroid and is usually more up to date. If swe calc() finds a preliminary designation, it looks for a name in this file.

The file seasnam.txt can be updated by the user. To do this, download the names list from the Minor Planet Center <a href="http://cfa-www.harvard.edu/iau/lists/MPNames.html">http://cfa-www.harvard.edu/iau/lists/MPNames.html</a>, rename it as seasnam.txt and move it into your ephemeris directory.

The file seasnam.txt need not be ordered in any way. There must be one asteroid per line, first its catalogue number, then its name. The asteroid number may or may not be in brackets.

#### Example:

```
(3192) A'Hearn
(3654) AAS
(8721) AMOS
(3568) ASCII
(2848) ASP
(677) Aaltje
```

#### 5. Fixed stars functions

The following functions are used to calculate positions of fixed stars.

# 5.1. Different functions for calculating fixed star positions

The function swe\_fixstar\_ut() does exactly the same as swe\_fixstar() except that it expects Universal Time rather than Terrestrial Time (Ephemeris Time) as an input value. (cf. swe\_calc\_ut() and swe\_calc()) For more details, see under 4.2 swe fixstar().

In the same way, the function swe\_fixstar2\_ut() does the same as swe\_fixstar2() except that it expects Universal Time as input time.

The functions swe\_fixstar2\_ut() and swe\_fixstar2() were introduced with SE 2.07. They do the same as swe\_fixstar\_ut() and swe\_fixstar() except that they are a lot faster and have a slightly different behavior, explained below.

For new projects, we recommend using the new functions <code>swe\_fixstar2\_ut()</code> and <code>swe\_fixstar2()</code>. Performance will be a lot better if a great number of fixed star calculations are done. If performance is a problem with your old projects, we recommend replacing the old functions by the new ones. However, the output should be checked carefully, because the behavior of old and new functions is not exactly identical. (explained below)

#### 5.2. swe fixstar2 ut(), swe fixstar2(), swe fixstar ut(), swe fixstar()

swephprg.doc ~13 ~

Swiss Ephemeris 2.08 Fixed stars functions

```
long iflag,
      double* xx,
      char* serr);
long swe_fixstar2(
      char *star,
      double tjd et,
      long iflag,
      double* xx,
      char* serr);
where:
         = name of fixed star to be searched, returned name of found star
star
tid ut = Julian day in Universal Time (swe_fixstar_ut())
tjd et = Julian day in Ephemeris Time (swe_fixstar())
         = an integer containing several flags that indicate what kind of computation is wanted
iflag
         = array of 6 doubles for longitude, latitude, distance, speed in long., speed in lat., and speed in dist.
```

serr[256] = character string to contain error messages in case of error.

The fixed stars functions only work if the fixed stars data file sefstars.txt is found in the ephemeris path. If the file sefstars.txt is not found, the old file fixstars.cat is searched and used instead, if present. However, **it is strongly recommended to \*not\*** use the old file anymore. The data in the file are outdated, and the algorithms are also not as accurate as those used with the file sefstars.txt.

The parameter star must provide for at least 41 characters for the returned star name. If a star is found, its name is returned in this field in the following format:

traditional\_name, nomenclature\_name e.g. "Aldebaran,alTau".

The nomenclature name is usually the so-called Bayer designation or the Flamsteed designation, in some cases also Henry Draper (HD) or other designations.

As for the explanation of the other parameters, see swe\_calc().

Barycentric positions are not implemented. The difference between geocentric and heliocentric fix star position is noticeable and arises from parallax and gravitational deflection.

The function has three modes to search for a star in the file sefstars.txt:

Behavior of new functions swe fixstar2() and swe fixstar2 ut():

• star contains a traditional name: the first star in the file sefstars.txt is used whose traditional name fits the given name. All names are mapped to lower case before comparison and white spaces are removed.

Changed behavior: The search string must match the complete star name. If you want to use a partial string, you have to add the wildcard character '%' to the search string, e.g. "aldeb%". (The old functions treat each search string as ending with a wildcard.)

The '%' can only be used at the end of the search string and only with the traditional star name, not with nomenclature names (i.e. not with Bayer or Flamsteed designations).

Note that the function overwrites the variable star. Both the full traditional name and the nomenclature name are copied into the variable, separated by a comma. E.g. if star is given the value "aldeb", then swe\_fixstar() overwrites this with "Aldebaran,alTau". The new string can also be used for a new search of the same star.

- star contains a comma, followed by a nomenclature name, e.g. ",alTau": the search string is understood to be the nomenclature name (the second field in a star record). Letter case is observed in the comparison for nomenclature names.
- star contains a positive number (in ASCII string format, e.g. "234"):

Changed behavior: The numbering of stars follows a sorted list of nomenclature names. (With the old functions, the n-th star of the fixed star file is returned.)

Behavior of old functions swe\_fixstar() and swe\_fixstar\_ut():

• star contains a traditional name: the first star in the file sefstars.txt is used whose traditional name fits the given name. All names are mapped to lower case before comparison and white spaces are removed.

If star has n characters, only the first n characters of the traditional name field are compared.

Note that the function overwrites the variable star. Both the full traditional name and the nomenclature name are

Swiss Ephemeris 2.08 Fixed stars functions

copied into the variable, separated by a comma. E.g. if star is given the value "aldeb", then swe fixstar() overwrites this with "Aldebaran, alTau". The new string can also be used for a new search of the same star.

- star begins with a comma, followed by a nomenclature name, e.g. ",alTau": the search string is understood to be the nomenclature name (the second field in a star record). Letter case is observed in the comparison for nomenclature names. Here again, star is overwritten by the string "Aldebaran, alTau".
- star contains a positive number (in ASCII string format, e.g. "234"):

The star data in the 234-th non-comment line in the file sefstars.txt are used. Comment lines that begin with # and are ignored. Here again, star will be overwritten by the traditional name and the nomenclature name, separated by a comma, e.g. "Aldebaran, alTau".

For correct spelling of nomenclature names, see file sefstars.txt. Nomenclature names are usually Bayer designations and are composed of a Greek letter and the name of a star constellation. The Greek letters were originally used to write numbers, therefore they actually number the stars of the constellation. The abbreviated nomenclature names we use in sefstars.txt are constructed from two lowercase letters for the Greek letter (e.g. "al" for "alpha", except "omi" and "ome") and three letters for the constellation (e.g. "Tau" for "Tauri").

The searching of stars by sequential number (instead of name or nomenclature name) is a practical feature if one wants to list all stars:

```
for i=1; i<10000; i++) { // choose any number greater than number of lines (stars) in file
sprintf(star, "%d", i);
returncode = swe_fixstar2(star, tjd, ...);
... whatever you want to do with the star positions ...
if (returncode == ERR)
break;
}
```

The function and the DLL should survive damaged sefstars.txt files which contain illegal data and star names exceeding the accepted length. Such fields are cut to acceptable length.

There are a few special entries in the file sefstars.txt:

```
# Gal. Center (SgrA*) according to Simbad database,
# speed of SgrA* according to Reid (2004), "The Proper Motion of Sagittarius A*",

```
# The following "object" played an important role in 2011 and 2017 dooms day predictions, # as well as in some conspiration theories. It consists of the infrared objects # IRAS 13458-0823 and IRAS 13459-0812. Central point measured by DK. Infrared Dragon, IDrag, ICRS, 13, 48, 0.0, -9, 0, 0.0, 0, 0, 0, 0, 0, 0, 0, 19, 477
```

You may edit the star catalogue and move the stars you prefer to the top of the file. With older versions of the Swiss Ephemeris, this will increase the speed of computations. The search mode is linear through the whole star file for each call of <a href="mailto:swe\_fixstar">swe\_fixstar</a>().

However, since SE 2.07 with the new functions swe\_fixstar2() and swe\_fixstar2\_ut(), this won't speed up calculations anymore, and the calculation speed will be the same for all stars.

#### **Attention:**

With older versions of the Swiss Ephemeris, <a href="mailto:swe\_fixstar">swe\_fixstar</a>() does not compute speeds of the fixed stars. Also, distance is always returned as 1 for all stars. Since SE 2.07 distances and daily motions are included in the return array.

Distances are given in AU. To convert them from AU to lightyears or parsec, please use the following defines, which are located in swephexp.h:

```
#define SE_AUNIT_TO_LIGHTYEAR (1.0/63241.077088071)
#define SE_AUNIT_TO_PARSEC (1.0/206264.8062471)
```

The daily motions of the fixed stars contain components of precession, nutation, aberration, parallax and the proper motions of the stars.

# 5.3. swe\_fixstar2\_mag(), swe\_fixstar\_mag()

```
long swe_fixstar_mag(
    char *star,
    double* mag,
    char* serr);
long swe_fixstar2_mag(
    char *star,
    double* mag,
    char* serr);
```

Function calculates the magnitude of a fixed star. The function returns OK or ERR. The magnitude value is returned in the parameter mag.

For the definition and use of the parameter star see function swe\_fixstar(). The parameter serr and is, as usually, an error string pointer.

The new function swe\_fixstar2\_mag() (since SE 2.07) is more efficient if great numbers of fixed stars are calculated.

Strictly speaking, the magnitudes returned by this function are valid for the year 2000 only. Variations in brightness due to the star's variability or due to the increase or decrease of the star's distance cannot be taken into account. With stars of constant absolute magnitude, the change in brightness can be ignored for the historical period. E.g. the current magnitude of Sirius is -1.46. In 3000 BCE it was -1.44.

# 6. Kepler elements, apsides and nodes, orbital periods

#### 6.1. swe\_nod\_aps\_ut()

The functions swe\_nod\_aps\_ut() and swe\_nod\_aps() compute planetary nodes and apsides (perihelia, aphelia, second focal points of the orbital ellipses). Both functions do exactly the same except that they expect a different time parameter (cf. swe\_calc\_ut() and swe\_calc()).

The definitions are:

swephprg.doc ~ 16 ~

```
int32 iflag,
      int32 method,
      double *xnasc,
      double *xndsc,
      double *xperi,
      double *xaphe,
      char *serr);
where:
              = Julian day in Universal Time
tjd_ut
              = planet number
ipl
iflag
              = same as with swe_calc_ut() and swe_fixstar_ut()
              = another integer that specifies the calculation method, see explanations below
method
             = array of 6 doubles for ascending node
xnasc
             = array of 6 doubles for descending node
xndsc
             = array of 6 doubles for perihelion
xperi
             = array of 6 doubles for aphelion
xaphe
serr[256]
             = character string to contain error messages in case of error.
```

#### 6.2. swe\_nod\_aps()

```
int32 swe_nod_aps(
    double tjd_et,
    int32 ipl,
    int32 iflag,
    int32 method,
    double *xnasc,
    double *xndsc,
    double *xperi,
    double *xaphe,
    char *serr);
same, but
tjd et = Julian day in Ephemeris Time
```

The parameter iflag allows the same specifications as with the function swe\_calc\_ut(). I.e., it contains the Ephemeris flag, the heliocentric, topocentric, speed, nutation flags etc. etc.

The parameter method tells the function what kind of nodes or apsides are required:

```
#define SE NODBIT MEAN 1
```

Mean nodes and apsides are calculated for the bodies that have them, i.e. for the Moon and the planets Mercury through Neptune, osculating ones for Pluto and the asteroids. This is the default method, also used if method=0.

```
#define SE NODBIT OSCU 2
```

Osculating nodes and apsides are calculated for all bodies.

```
#define SE_NODBIT_OSCU_BAR 4
```

Osculating nodes and apsides are calculated for all bodies. With planets beyond Jupiter, the nodes and apsides are calculated from *barycentric* positions and speed. Cf. the explanations in swisseph.doc.

If this bit is combined with SE\_NODBIT\_MEAN, mean values are given for the planets Mercury - Neptune.

```
#define SE NODBIT FOPOINT 256
```

The second focal point of the orbital ellipse is computed and returned in the array of the aphelion. This bit can be combined with any other bit.

swephprg.doc ~ 17 ~

# 6.3. swe\_get\_orbital\_elements()

This function calculates osculating elements (Kepler elements) and orbital periods for a planet, the Earth-Moon barycenter, or an asteroid. The elements are calculated relative to the mean ecliptic J2000.

The elements define the orbital ellipse under the premise that it is a two-body system and there are no perturbations from other celestial bodies. The elements are particularly bad for the Moon, which is strongly perturbed by the Sun. It is not recommended to calculate ephemerides using Kepler elements.

```
int32 swe get orbital elements(
     double tjd_et,
     int32 ipl.
     int32 iflag,
     double *dret,
     char *serr);
/* Function calculates osculating orbital elements (Kepler elements) of a planet
* or asteroid or the EMB. The function returns error,
* if called for the Sun, the lunar nodes, or the apsides.
* Input parameters:
* tjd_et Julian day number, in TT (ET)
* ipl object number
* iflag can contain
* - ephemeris flag: SEFLG_JPLEPH, SEFLG_SWIEPH, SEFLG_MOSEPH
* - center:
* Sun: SEFLG_HELCTR (assumed as default) or
* SS Barycentre: SEFLG_BARYCTR (rel. to solar system barycentre)
* (only possible for planets beyond Jupiter)
* For elements of the Moon, the calculation is geocentric.
* - sum all masses inside the orbit to be computed (method
* of Astronomical Almanac):
* SEFLG ORBEL AA
* - reference ecliptic: SEFLG J2000;
* if missing, mean ecliptic of date is chosen (still not implemented)
* output parameters:
* dret[] array of return values, declare as dret[50]
* dret[0] semimajor axis (a)
* dret[1] eccentricity (e)
* dret[2] inclination (in)
* dret[3] longitude of ascending node (upper case omega OM)
* dret[4] argument of periapsis (lower case omega om)
* dret[5] longitude of periapsis (peri)
* dret[6] mean anomaly at epoch (M0)
* dret[7] true anomaly at epoch (N0)
* dret[8] eccentric anomaly at epoch (E0)
* dret[9] mean longitude at epoch (LM)
* dret[10] sidereal orbital period in tropical years
* dret[11] mean daily motion
* dret[12] tropical period in years
* dret[13] synodic period in days,
* negative, if inner planet (Venus, Mercury, Aten asteroids) or Moon
* dret[14] time of perihelion passage
* dret[15] perihelion distance
* dret[16] aphelion distance
```

swephprg.doc ~ 18 ~

# 6.4. swe\_orbit\_max\_min\_true\_distance()

This function calculates the maximum possible distance, the minimum possible distance, and the current true distance of planet, the EMB, or an asteroid. The calculation can be done either heliocentrically or geocentrically. With heliocentric calculations, it is based on the momentary Kepler ellipse of the planet. With geocentric calculations, it is based on the Kepler ellipses of the planet and the EMB. The geocentric calculation is rather expensive..

```
int32 swe_orbit_max_min_true_distance(
     double tid et,
     int32 ipl,
     int32 iflag,
     double *dmax,
     double *dmin,
     double *dtrue,
     char *serr);
/* Input:
* tid et epoch
* ipl planet number
* iflag ephemeris flag and optional heliocentric flag (SEFLG HELCTR)
* output:
* dmax maximum distance (pointer to double)
* dmin minimum distance (pointer to double)
* dtrue true distance (pointer to double)
* serr error string
```

# 7. Eclipses, risings, settings, meridian transits, planetary phenomena

There are the following functions for eclipse and occultation calculations.

Solar eclipses:

- swe\_sol\_eclipse\_when\_loc(tjd...) finds the next eclipse for a given geographic position;
- swe\_sol\_eclipse\_when\_glob(tjd...) finds the next eclipse globally;
- swe\_sol\_eclipse\_where() computes the geographic location of a solar eclipse for a given tjd;
- **swe\_sol\_eclipse\_how()** computes attributes of a solar eclipse for a given tjd, geographic longitude, latitude and height.

Occultations of planets by the moon:

These functions can also be used for solar eclipses. But they are slightly less efficient.

- swe\_lun\_occult\_when\_loc(tjd...) finds the next occultation for a body and a given geographic position;
- swe\_lun\_occult\_when\_glob(tjd...) finds the next occultation of a given body globally;
- swe\_lun\_occult\_where() computes the geographic location of an occultation for a given tjd.

Lunar eclipses:

- swe\_lun\_eclipse\_when\_loc(tjd...) finds the next lunar eclipse for a given geographic position;
- swe\_lun\_eclipse\_when(tjd...) finds the next lunar eclipse;
- swe\_lun\_eclipse\_how() computes the attributes of a lunar eclipse for a given tjd.

Risings, settings, and meridian transits of planets and stars:

- swe\_rise\_trans();
- swe\_rise\_trans\_true\_hor() returns rising and setting times for a local horizon with altitude != 0.

Planetary phenomena:

swe\_pheno\_ut() and swe\_pheno() compute phase angle, phase, elongation, apparent diameter, and apparent
magnitude of the Sun, the Moon, all planets and asteroids.

swephprg.doc ~ 19 ~

#### 7.1. Example of a typical eclipse calculation

Find the next total eclipse, calculate the geographical position where it is maximal and the four contacts for that position (for a detailed explanation of all eclipse functions see the next chapters):

```
double tret[10], attr[20], geopos[10];
char serr[255];
int32 whicheph = 0; /* default ephemeris */
double tjd start = 2451545; /* Julian day number for 1 Jan 2000 */
int32 ifltype = SE_ECL_TOTAL | SE_ECL_CENTRAL | SE_ECL_NONCENTRAL;
/* find next eclipse anywhere on Earth */
eclflag = swe_sol_eclipse_when_glob(tjd_start, whicheph, ifltype, tret, 0, serr);
if (eclflag == ERR)
return ERR;
/* the time of the greatest eclipse has been returned in tret[0];
* now we can find geographical position of the eclipse maximum */
tid start = tret[0];
eclflag = swe_sol_eclipse_where(tjd_start, whicheph, geopos, attr, serr);
if (eclflag == ERR)
return ERR;
/* the geographical position of the eclipse maximum is in geopos[0] and geopos[1];
* now we can calculate the four contacts for this place. The start time is chosen
* a day before the maximum eclipse: */
tjd start = tret[0] - 1;
eclflag = swe sol eclipse when loc(tjd start, whicheph, geopos, tret, attr, 0, serr);
if (eclflag == ERR)
return ERR;
/* now tret[] contains the following values:
* tret[0] = time of greatest eclipse (Julian day number)
* tret[1] = first contact
* tret[2] = second contact
* tret[3] = third contact
* tret[4] = fourth contact */
```

# 7.2. swe\_sol\_eclipse\_when\_loc()

To find the next eclipse for a given geographic position, use swe\_sol\_eclipse\_when\_loc().

```
int32 swe_sol_eclipse_when_loc(
     double tjd start,
                         /* start date for search, Jul. day UT */
                          /* ephemeris flag */
     int32 if1,
     double *geopos,
                          /* 3 doubles for geographic lon, lat, height.
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
     double *tret,
                          /* return array, 10 doubles, see below */
                          /* return array, 20 doubles, see below */
     double *attr,
                         /* TRUE, if backward search */
     AS_BOOL backward,
     char *serr);
                          /* return error string */
      The function returns:
/* retflag -1 (ERR) on error (e.g. if swe_calc() for sun or moon fails)
          SE_ECL_TOTAL or SE_ECL_ANNULAR or SE_ECL_PARTIAL
```

swephprg.doc ~ 20 ~

```
SE_ECL_VISIBLE,
          SE_ECL_MAX_VISIBLE,

attr[9]
attr[10] saros series member number (if available; otherwise -99999999)
*/
```

# 7.3. swe\_sol\_eclipse\_when\_glob()

To find the next eclipse globally:

This function requires the time parameter tjd\_start in *Universal Time* and also yields the return values (tret[]) in UT. For conversions between ET and UT, use the function swe deltat().

Note: An implementation of this function with parameters in Ephemeris Time would have been possible. The question when the next solar eclipse will happen anywhere on Earth is independent of the rotational position of the Earth and therefore independent of Delta T. However, the function is often used in combination with other eclipse functions (see example below), for which input and output in ET makes no sense, because they concern local circumstances of an eclipse and therefore *are* dependent on the rotational position of the Earth. For this reason, UT has been chosen for the time parameters of all eclipse functions.

ifltype specifies the eclipse type wanted. It can be a combination of the following bits (see swephexp.h):

```
#define SE_ECL_CENTRAL 1
#define SE_ECL_NONCENTRAL 2
#define SE_ECL_TOTAL 4
#define SE_ECL_ANNULAR 8
#define SE_ECL_PARTIAL 16
#define SE_ECL_ANNULAR_TOTAL 32
```

swephprg.doc ~ 21 ~

```
Recommended values for ifltype:
/* search for any eclipse, no matter which type */
ifltype = 0;
/* search a total eclipse; note: non-central total eclipses are very rare */
ifltype = SE_ECL_TOTAL | SE_ECL_CENTRAL | SE_ECL_NONCENTRAL;
/* search an annular eclipse */
ifltype = SE ECL ANNULAR | SE ECL CENTRAL | SE ECL NONCENTRAL;
/* search an annular-total (hybrid) eclipse */
ifltype_ = SE_ECL_ANNULAR_TOTAL | SE_ECL_CENTRAL | SE_ECL_NONCENTRAL;
/* search a partial eclipse */
ifltype = SE_ECL_PARTIAL;
If your code does not work, please study the sample code in swetest.c.
The function returns:
/* retflag -1 (ERR) on error (e.g. if swe_calc() for sun or moon fails)
          SE ECL TOTAL or SE ECL ANNULAR or SE ECL PARTIAL or SE ECL ANNULAR TOTAL
          SE_ECL_CENTRAL
          SE_ECL_NONCENTRAL
tret[0]
          time of maximum eclipse
tret[1]
          time, when eclipse takes place at local apparent noon
tret[2] time of eclipse begin
tret[3] time of eclipse end
tret[4] time of totality begin
tret[5] time of totality end
tret[6] time of center line begin
tret[7] time of center line end
          time when annular-total eclipse becomes total, not implemented so far
tret[8]
          time when annular-total eclipse becomes annular again, not implemented so far
tret[9]
declare as tret[10] at least!
*/
```

# 7.4. swe\_sol\_eclipse\_how ()

To calculate the attributes of an eclipse for a given geographic position and time:

```
int32 swe_sol_eclipse_how(
                         /* time, Jul. day UT */
     double tjd ut,
                         /* ephemeris flag */
     int32 if1,
                         /* geogr. longitude, latitude, height above sea.
     double *geopos
                         * eastern longitude is positive,
                          * western longitude is negative,
                         * northern latitude is positive,
                         * southern latitude is negative */
                         /* return array, 20 doubles, see below */
     double *attr,
     char *serr);
                         /* return error string */
/* retflag -1 (ERR) on error (e.g. if swe calc() for sun or moon fails)
          SE_ECL_TOTAL or SE_ECL_ANNULAR or SE_ECL_PARTIAL
          0, if no eclipse is visible at geogr. position.
          fraction of solar diameter covered by moon;
attr[0]
          with total/annular eclipses, it results in magnitude acc. to IMCCE.
         ratio of lunar diameter to solar one
attr[1]
          fraction of solar disc covered by moon (obscuration)
attr[2]
        diameter of core shadow in km
attr[3]
```

swephprg.doc ~ 22 ~

```
attr[4] azimuth of sun at tjd
attr[5] true altitude of sun above horizon at tjd
attr[6] apparent altitude of sun above horizon at tjd
attr[7] elongation of moon in degrees
attr[8] magnitude acc. to NASA;
= attr[0] for partial and attr[1] for annular and total eclipses
attr[9] saros series number (if available; otherwise -99999999)
attr[10] saros series member number (if available; otherwise -99999999) */
7.5. swe_sol_eclipse_where ()
```

This function can be used to find out the geographic position, where, for a given time, a central eclipse is central or where a non-central eclipse is maximal.

If you want to draw the eclipse path of a total or annular eclipse on a map, first compute the start and end time of the total or annular phase with swe\_sol\_eclipse\_when\_glob(), then call swe\_sol\_eclipse\_how() for several time intervals to get geographic positions on the central path. The northern and southern limits of the umbra and penumbra are not implemented yet.

```
int32 swe sol eclipse where(
                          /* time, Jul. day UT */
     double tjd_ut,
     int32 if1,
                         /* ephemeris flag */
     double *geopos,
                          /* return array, 2 doubles, geo. long. and lat.
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
                          /* return array, 20 doubles, see below */
     double *attr,
     char *serr);
                          /* return error string */
The function returns:
/* -1 (ERR)
               on error (e.g. if swe calc() for sun or moon fails)
          if there is no solar eclipse at tjd

```

### 7.6. swe\_lun\_occult\_when\_loc()

To find the next occultation of a planet or star by the moon for a given location, use swe\_lun\_occult\_when\_loc().

The same function can also be used for local solar eclipses instead of swe\_sol\_eclipse\_when\_loc(), but is a bit less efficient.

```
/* Same declaration as swe sol eclipse when loc().
* In addition:
* int32 ipl
                    planet number of occulted body
 char* starname
                    name of occulted star. Must be NULL or "", if a planetary
                    occultation is to be calculated. For use of this field, see swe_fixstar().
 int32 if1
                    ephemeris flag. If you want to have only one conjunction
                    of the moon with the body tested, add the following flag:
                    backward |= SE ECL ONE TRY. If this flag is not set,
                    the function will search for an occultation until it
                    finds one. For bodies with ecliptical latitudes > 5,
                    the function may search unsuccessfully until it reaches
                    the end of the ephemeris.
int32 swe_lun_occult_when_loc(
     double tid start,
                        /* start date for search, Jul. day UT */
     int32 ipl,
                         /* planet number */
     char* starname,
                         /* star name, must be NULL or "" if not a star */
                          /* ephemeris flag */
     int32 if1,
                          /* 3 doubles for geogr. longitude, latitude, height above sea.
     double *geopos,
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
                          /* return array, 10 doubles, see below */
     double *tret,
                          /* return array, 20 doubles, see below */
     double *attr,
     AS_BOOL backward,
                         /* TRUE, if backward search */
     char *serr);
                          /* return error string */
```

Occultations of some stars may be very rare or do not occur at all. Usually the function searches an event until it finds one or reaches the end of the ephemeris. In order to avoid endless loops, the function can be called using the flag ifl = SE ECL ONE TRY. If called with this flag, the function searches the next date when the Moon is in conjunction with the object and finds out whether it is an occultation. The function does not check any other conjunctions in the future or past.

- If the return value is > 0, there is an occultation and tret and attr contain the information about it;
- If the return value is = 0, there is no occupation; tret[0] contains the date of closest conjunction;

~ 24 ~ swephprg.doc

• If the return value is = -1, there is an error.

In order to find events in a particular time range ( $tjd\_start < tjd < tjd\_stop$ ), one can write a loop and call the function as often as date ( $tjd < tjd\_stop$ ). After each call, increase the tjd = tret[0] + 2.

If one has a set of stars or planets for which one wants to find occultations for the same time range, one has to run the same loop for each of these object. If the events have to be listed in chronological order, one has to sort them before output.

The function returns:

```
/* retflag
-1 (ERR) on error (e.g. if swe_calc() for sun or moon fails)
0 (if no occultation/no eclipse found)
          SE ECL TOTAL or SE ECL ANNULAR or SE ECL PARTIAL
          SE_ECL_VISIBLE,
          SE ECL MAX VISIBLE,
          SE_ECL_1ST_VISIBLE, SE_ECL_2ND_VISIBLE
          SE_ECL_3ST_VISIBLE, SE_ECL_4ND_VISIBLE
These return values (except the SE ECL ANNULAR) also appear with occultations.
          time of maximum eclipse

```

#### 7.7. swe lun occult when glob()

To find the next occultation of a planet or star by the moon globally (not for a particular geographic location), use swe lun occult when glob().

The same function can also be used for global solar eclipses instead of swe\_sol\_eclipse\_when\_glob(), but is a bit less efficient.

swephprg.doc ~ 25 ~

```
the end of the ephemeris.
*/
int32 swe_lun_occult_when_glob(
     double tjd start,
                        /* start date for search, Jul. day UT */
     int32 ipl,
                         /* planet number */
     char* starname,
                         /* star name, must be NULL or "" if not a star */
                         /* ephemeris flag */
     int32 if1,
     int32 ifltype,
                         /* eclipse type wanted */
     double *tret,
                         /* return array, 10 doubles, see below */
                         /* TRUE, if backward search */
     AS BOOL backward,
                         /* return error string */
     char *serr);
An explanation of the ifl |= SE_ECL_ONE_TRY is given above in paragraph about the function
swe_lun_occult_when_loc().
The function returns:
/* retflag
-1 (ERR) on error (e.g. if swe_calc() for sun or moon fails)
0 (if no occultation / eclipse has been found)
          SE_ECL_TOTAL or SE_ECL_ANNULAR or SE_ECL_PARTIAL or SE_ECL_ANNULAR_TOTAL

          time when annular-total eclipse becomes annular again not implemented so far
tret[9]
declare as tret[10] at least!
*/
```

#### 7.8. swe\_lun\_occult\_where ()

Similar to swe\_sol\_eclipse\_where(), this function can be used to find out the geographic position, where, for a given time, a central eclipse is central or where a non-central eclipse is maximal. With occultations, it tells us, at which geographic location the occulted body is in the middle of the lunar disc or closest to it. Because occultations are always visible from a very large area, this is not very interesting information. But it may become more interesting as soon as the limits of the umbra (and penumbra) will be implemented.

```
int32 swe_lun_occult_where(
     double tjd ut,
                         /* time, Jul. day UT */
     int32 ipl,
                          /* planet number */
     char* starname,
                         /* star name, must be NULL or "" if not a star */
                          /* ephemeris flag */
     int32 if1,
                          /* return array, 2 doubles, geo. long. and lat.
     double *geopos,
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
     double *attr,
                          /* return array, 20 doubles, see below */
     char *serr);
                          /* return error string */
```

swephprg.doc ~ 26 ~

```
The function returns:
/* -1 (ERR)

declare as attr[20] at least!
*/
```

#### 7.12. swe\_rise\_trans() and swe\_rise\_trans\_true\_hor() (risings, settings, meridian transits)

The function swe\_rise\_trans() computes the times of rising, setting and meridian transits for all planets, asteroids, the moon, and the fixed stars. The function swe\_rise\_trans\_true\_hor() does the same for a local horizon that has an altitude != 0.

The function returns a rising time of an object:

- if at t0 the object is below the horizon and a rising takes place before the next culmination of the object;
- if at t0 the object is above the horizon and a rising takes place between the next lower and upper culminations of the object.

And it returns a setting time of an object,

- if at t0 the object is above the horizon and a setting takes place before the next lower culmination of the object;
- if at t0 the object is below the horizon and a setting takes place between the next upper and lower culminations.

Note, "culmination" does not mean meridian transit, especially not with the Sun, Moon, and planets. The culmination of a moving body with changing declination does not take place exactly on the meridian but shortly before or after the

swephprg.doc ~ 29 ~

meridian transit. In polar regions, it even happens that the moon "rises" shortly after the culmination, on the west side of the meridian. I. e., the upper limb if its disk will become visible for a short time. The function swe\_rise\_trans() should catch these cases.

Function definitions are as follows:

```
int32 swe rise trans(
     double tjd_ut,
                          /* search after this time (UT) */
     int32 ipl,
                          /* planet number, if planet or moon */
     char *starname,
                          /* star name, if star; must be NULL or empty, if ipl is used */
                          /* ephemeris flag */
     int32 epheflag,
                          /st integer specifying that rise, set, or one of the two meridian
     int32 rsmi,
     transits is wanted. see definition below */
     double *geopos,
                          /* array of three doubles containing
                          * geograph. long., lat., height of observer */
                          /* atmospheric pressure in mbar/hPa */
     double atpress
                          /* atmospheric temperature in deg. C */
     double attemp,
     double *tret,
                          /* return address (double) for rise time etc. */
     char *serr);
                          /* return address for error message */
int32 swe rise trans true hor(
     double tjd_ut,
                          /* search after this time (UT) */
     int32 ipl,
                          /* planet number, if planet or moon */
     char *starname,
                          /* star name, if star; must be NULL or empty, if ipl is used */
                          /* ephemeris flag */
     int32 epheflag,
                          /* integer specifying that rise, set, or one of the two meridian
     int32 rsmi,
     transits is wanted. see definition below */
     double *geopos,
                          /* array of three doubles containing
                          * geograph. long., lat., height of observer */
                          /* atmospheric pressure in mbar/hPa */
     double atpress,
     double attemp,
                          /* atmospheric temperature in deg. C */
                          /* height of local horizon in deg at the point where the body rises or
     double horhgt,
     sets */
                          /* return address (double) for rise time etc. */
     double *tret,
     char *serr);
                          /* return address for error message */
```

The second function has one additional parameter horhgt for the height of the local horizon at the point where the body rises or sets.

The variable rsmi can have the following values:

```
/* for swe_rise_trans() and swe_rise_trans_true_hor() */
#define SE CALC RISE
                                    1
#define SE CALC SET
                                    2
#define SE_CALC_MTRANSIT
                                    4
                                         /* upper meridian transit (southern for northern geo.
latitudes) */
#define SE_CALC_ITRANSIT
                                         /* lower meridian transit (northern, below the horizon)
/* the following bits can be added (or'ed) to SE_CALC_RISE or SE_CALC_SET */
#define SE_BIT_DISC_CENTER
                                    256 /* for rising or setting of disc center */
#define SE_BIT_DISC_BOTTOM
                                    8192 /* for rising or setting of lower limb of disc */
#define SE BIT GEOCTR NO ECL LAT
                                    128 /* use topocentric position of object and ignore its
ecliptic latitude */
                                    512 /* if refraction is not to be considered */
#define SE_BIT_NO_REFRACTION

```

swephprg.doc ~ 30 ~

```
SE_BIT_GEOCTR_NO_ECL_LAT)
/* risings according to Hindu astrology */
rsmi = 0 will return risings.
```

The rising times depend on the atmospheric pressure and temperature. atpress expects the atmospheric pressure in millibar (hectopascal); attemp the temperature in degrees Celsius.

If atpress is given the value 0, the function estimates the pressure from the geographical altitude given in geopos[2] and attemp. If geopos[2] is 0, atpress will be estimated for sea level.

Function return values are:

- 0 if a rising, setting or transit event was found;
- -1 if an error occurred (usually an ephemeris problem);
- -2 if a rising or setting event was not found because the object is circumpolar.

## 7.12.1. Sunrise in Astronomy and in Hindu Astrology

The astronomical sunrise is defined as the time when the upper limb of the solar disk is seen appearing at the horizon. The astronomical sunset is defined as the moment the upper limb of the solar disk disappears below the horizon.

The function swe\_rise\_trans() by default follows this definition of astronomical sunrises and sunsets. Also, astronomical almanacs and newspapers publish astronomical sunrises and sunset according to this definition.

Hindu astrology and Hindu calendars use a different definition of sunrise and sunset. They consider the Sun as rising or setting, when the center of the solar disk is exactly at the horizon. In addition, the Hindu method ignores atmospheric refraction. Moreover, the geocentric rather than topocentric position is used and the small ecliptic latitude of the Sun is ignored.

In order to calculate correct Hindu rising and setting times, the flags SE\_BIT\_NO\_REFRACTION and SE\_BIT\_DISC\_CENTER must be added (or'ed) to the parameter rsmi. From Swiss Ephemeris version 2.06 on, a flag SE\_BIT\_HINDU\_RISING is supported. It includes the flags SE\_BIT\_NO\_REFRACTION, SE\_BIT\_DISC\_CENTER and SE\_BIT\_GEOCTR\_NO\_ECL\_LAT.

In order to calculate the sunrise of a given date and geographic location, one can proceed as in the following program (tested code!):

```
int main()
{
char serr[AS MAXCH];
double epheflag = SEFLG_SWIEPH;
int gregflag = SE_GREG_CAL;
int year = 2017;
int month = 4;
int day = 12;
int geo longitude = 76.5; // positive for east, negative for west of Greenwich
int geo latitude = 30.0;
int geo_altitude = 0.0;
double hour;
// array for atmospheric conditions
double datm[2];
datm[0] = 1013.25; // atmospheric pressure;
// irrelevant with Hindu method, can be set to 0
datm[1] = 15; // atmospheric temperature;
// irrelevant with Hindu method, can be set to 0
// array for geographic position
double geopos[3];
geopos[0] = geo_longitude;
geopos[1] = geo_latitude;
geopos[2] = geo_altitude; // height above sea level in meters;
// irrelevant with Hindu method, can be set to 0
```

swephprg.doc ~ 31 ~

```
swe_set_topo(geopos[0], geopos[1], geopos[2]);
int ipl = SE_SUN; // object whose rising is wanted
char starname[255]; // name of star, if a star's rising is wanted
// is "" or NULL, if Sun, Moon, or planet is calculated
double trise; // for rising time
double tset; // for setting time
// calculate the Julian day number of the date at 0:00 UT:
double tjd = swe_julday(year,month,day,0,gregflag);
// convert geographic longitude to time (day fraction) and subtract it from tjd
// this method should be good for all geographic latitudes except near in
// polar regions
double dt = geo longitude / 360.0;
tid = tid - dt;
// calculation flag for Hindu risings/settings
int rsmi = SE_CALC_RISE | SE_BIT_HINDU_RISING;
// or SE_CALC_RISE + SE_BIT_HINDU_RISING;
// or SE_CALC_RISE | SE_BIT_DISC_CENTER | SE_BIT_NO_REFRACTION | SE_BIT_GEOCTR_NO_ECL_LAT;
int return_code = swe_rise_trans(tjd, ipl, starname, epheflag, rsmi, geopos, datm[0], datm[1],
&trise, serr);
if (return code == ERR) {
// error action
printf("%s\n", serr);
// conversion to local time zone must be made by the user. The Swiss Ephemeris
// does not have a function for that.
// After that, the Julian day number of the rising time can be converted into
// date and time:
swe_revjul(trise, gregflag, &year, &month, &day, &hour);
printf("sunrise: date=%d/%d/%d, hour=%.6f UT\n", year, month, day, hour);
// To calculate the time of the sunset, you can either use the same
// tjd increased or trise as start date for the search.
rsmi = SE CALC SET | SE BIT DISC CENTER | SE BIT NO REFRACTION;
return_code = swe_rise_trans(tjd, ipl, starname, epheflag, rsmi, geopos, datm[0], datm[1], &tset,
serr);
if (return code == ERR) {
// error action
printf("%s\n", serr);
printf("sunset : date=%d/%d/%d, hour=%.6f UT\n", year, month, day, hour);
```

## 7.13. swe\_pheno\_ut() and swe\_pheno(), planetary phenomena

These functions compute phase, phase angle, elongation, apparent diameter, apparent magnitude for the Sun, the Moon, all planets and asteroids. The two functions do exactly the same but expect a different time parameter.

swephprg.doc ~ 32 ~

```
double tjd_et,
                          /* time Jul. Day ET */
                          /* planet number */
     int32 ipl,
     int32 iflag,
                          /* ephemeris flag */
                          /* return array, 20 doubles, see below */
     double *attr,
     char *serr);
                          /* return error string */
The function returns:
/*
attr[0] = phase angle (Earth-planet-sun)
attr[1] = phase (illumined fraction of disc)
attr[2] = elongation of planet
attr[3] = apparent diameter of disc
attr[4] = apparent magnitude
declare as attr[20] at least!
NOTE: the lunar magnitude is quite a complicated thing,
but our algorithm is very simple.
The phase of the moon, its distance from the Earth and
the sun is considered, but no other factors.
iflag also allows SEFLG TRUEPOS, SEFLG HELCTR
*/
```

## 7.14. swe azalt(), horizontal coordinates, azimuth, altitude

**swe\_azalt()** computes the horizontal coordinates (azimuth and altitude) of a planet or a star from either ecliptical or equatorial coordinates.

```
void swe_azalt(
                         // UT
     double tjd_ut,
     int32 calc_flag,
                         // SE ECL2HOR or SE EQU2HOR
     double *geopos,
                         // array of 3 doubles: geograph. long., lat., height
     double atpress,
                         // atmospheric pressure in mbar (hPa)
                         // atmospheric temperature in degrees Celsius
     double attemp,
                         // array of 3 doubles: position of body in either ecliptical or
     double *xin,
     equatorial coordinates, depending on calc_flag
                         // return array of 3 doubles, containing azimuth, true altitude,
     double *xaz);
     apparent altitude
If calc flag = SE ECL2HOR, set xin[0] = ecl. long., xin[1] = ecl. lat., (xin[2] = distance (not
required));
else
if calc flag = SE EQU2HOR, set xin[0] = right ascension, xin[1] = declination, (xin[2] = distance
(not required));
#define SE_ECL2HOR
#define SE EQU2HOR
```

The return values are:

- xaz[0] = azimuth, i.e. position degree, measured from the south point to west;
- xaz[1] = true altitude above horizon in degrees;
- xaz[2] = apparent (refracted) altitude above horizon in degrees.

The apparent altitude of a body depends on the atmospheric pressure and temperature. If only the true altitude is required, these parameters can be neglected.

If atpress is given the value 0, the function estimates the pressure from the geographical altitude given in geopos[2] and attemp. If geopos[2] is 0, atpress will be estimated for sea level.

swephprg.doc ~ 33 ~

## 7.15. swe azalt rev()

The function swe\_azalt\_rev() is not precisely the reverse of swe\_azalt(). It computes either ecliptical or equatorial coordinates from azimuth and true altitude. If only an apparent altitude is given, the true altitude has to be computed first with the function swe\_refrac() (see below).

It is defined as follows:

For the definition of the azimuth and true altitude, see chapter 4.9 on swe\_azalt().

```
#define SE_HOR2ECL 0
#define SE_HOR2EQU 1
```

## 7.16. swe\_refrac(), swe\_refrac\_extended(), refraction

The refraction function **swe\_refrac()** calculates either the true altitude from the apparent altitude or the apparent altitude. Its definition is:

The refraction depends on the atmospheric pressure and temperature at the location of the observer.

If atpress is given the value 0, the function estimates the pressure from the geographical altitude given in geopos[2] and attemp. If geopos[2] is 0, atpress will be estimated for sea level.

There is also a more sophisticated function **swe\_refrac\_extended()**. It allows correct calculation of refraction for altitudes above sea > 0, where the ideal horizon and planets that are visible may have a negative height. (for swe\_refrac(), negative apparent heights do not exist!)

```
double swe_refrac_extended(
```

```
/* altitude of object above geometric horizon in degrees, where
double inalt,
geometric horizon = plane perpendicular to gravity */
double geoalt,
                    /* altitude of observer above sea level in meters */
                    /* atmospheric pressure in mbar (hPa) */
double atpress,
                    /* (dattemp/dgeoalt) = [°K/m] */
double lapse_rate,
double attemp,
                    /* atmospheric temperature in degrees Celsius */
int32 calc_flag,
double *dret);
                    /* array of 4 doubles; declare 20 ! */
                    * - dret[0] true altitude, if possible; otherwise input value
                    * - dret[1] apparent altitude, if possible; otherwise input value
                    * - dret[2] refraction
                    * - dret[3] dip of the horizon
                    /* either SE TRUE TO APP or SE APP TO TRUE */
```

swephprg.doc ~ 34 ~

#### Function returns:

- **case 1**, conversion from true altitude to apparent altitude:
  - o apparent altitude, if body appears above is observable above ideal horizon;
  - o true altitude (the input value); otherwise "ideal horizon" is the horizon as seen above an ideal sphere (as seen from a plane over the ocean with a clear sky)
- case 2, conversion from apparent altitude to true altitude:
  - o the true altitude resulting from the input apparent altitude, if this value is a plausible apparent altitude, i.e. if it is a position above the ideal horizon;
  - o the input altitude; otherwise in addition the array dret[] returns the following values:
    - dret[0] true altitude, if possible; otherwise input value;
    - dret[1] apparent altitude, if possible; otherwise input value;
    - dret[2] refraction;
    - dret[3] dip of the horizon.

The body is above the horizon if the dret[0] != dret[1].

## 7.17. Heliacal risings etc.: swe\_heliacal\_ut()

The function swe heliacal ut() the Julian day of the next heliacal phenomenon after a given start date. It works between geographic latitudes 60s - 60n.

```
int32 swe_heliacal_ut(
     double tjdstart,
                         /* Julian day number of start date for the search of the heliacal event
     double *dgeo
                         /* geographic position (details below) */
     double *datm,
                         /* atmospheric conditions (details below) */
     double *dobs,
                         /* observer description (details below) */
                         /* name string of fixed star or planet */
     char *objectname,
                         /* event type (details below) */
     int32 event_type,
                         /* calculation flag, bitmap (details below) */
     int32 helflag,
     double *dret,
                         /* result: array of at least 50 doubles, of which 3 are used at the
     moment */
     char * serr);
                         /* error string */
```

Function returns OK or ERR.

Details for dgeo[] (array of doubles):

```
dgeo[0]: geographic longitude;
dgeo[1]: geographic latitude;
dgeo[2]: geographic altitude (eye height) in meters.
```

Details for datm[] (array of doubles):

```
datm[0]: atmospheric pressure in mbar (hPa);
datm[1]: atmospheric temperature in degrees Celsius;
datm[2]: relative humidity in %;
datm[3]: if datm[3]>=1, then it is Meteorological Range [km];
          if 1>datm[3]>0, then it is the total atmospheric coefficient (ktot);
```

datm[3]=0, then the other atmospheric parameters determine the total atmospheric coefficient (ktot)

#### Default values:

If this is too much for you, set all these values to 0. The software will then set the following defaults:

Pressure 1013.25, temperature 15, relative humidity 40. The values will be modified depending on the altitude of the observer above sea level.

If the extinction coefficient (meteorological range) datm[3] is 0, the software will calculate its value from datm[0..2]. Details for dobs [] (array of six doubles):

~ 35 ~ swephprg.doc

```
dobs[0]: age of observer in years (default = 36)
  dobs[1]: Snellen ratio of observers eyes (default = 1 = normal)
The following parameters are only relevant if the flag SE_HELFLAG_OPTICAL_PARAMS is set:
  dobs[2]: 0 = monocular, 1 = binocular (actually a boolean)
  dobs[3]: telescope magnification: 0 = default to naked eye (binocular), 1 = naked eye
  dobs[4]: optical aperture (telescope diameter) in mm
  dobs[5]: optical transmission
Details for event_type:
  event_type = SE_HELIACAL_RISING (1): morning first (exists for all visible planets and stars);
  event_type = SE_HELIACAL_SETTING (2): evening last (exists for Mercury, Venus, and the Moon);
  event_type = SE_EVENING_FIRST (3): evening last (exists for Mercury, Venus, and the Moon).
```

#### Details for helflag:

helflag contains ephemeris flag, like iflag in swe\_calc() etc. In addition it can contain the following bits:

SE\_HELFLAG\_OPTICAL\_PARAMS (512): Use this with calculations for optical instruments.

Unless this bit is set, the values of dobs[2-5] are ignored.

SE\_HELFLAG\_NO\_DETAILS (1024): provide the date, but not details like visibility start, optimum, and end. This bit makes the program a bit faster.

SE\_HELFLAG\_VISLIM\_DARK (4096): function behaves as if the Sun were at nadir.

SE\_HELFLAG\_VISLIM\_NOMOON (8192): function behaves as if the Moon were at nadir, i. e. the Moon as a factor disturbing the observation is excluded. This flag is useful if one is not really interested in the heliacal date of that particular year, but in the heliacal date of that epoch.

Some other SE\_HELFLAG\_ bits found in swephexp.h were made for mere test purposes and may change in future releases. Please do not use them and do not request any support or information related to them.

Details for return array dret[] (array of doubles):

```
dret[0]: start visibility (Julian day number);
dret[1]: optimum visibility (Julian day number), zero if helflag >= SE_HELFLAG_AV;
dret[2]: end of visibility (Julian day number), zero if helflag >= SE_HELFLAG_AV.
```

## Strange phenomena:

• Venus' heliacal rising can occur before her heliacal setting. In such cases the planet may be seen both as a morning star and an evening star for a couple of days. Example:

```
swetest -hev1 -p3 -b1.1.2008 -geopos8,47,900 -at1000,10,20,0.15 -obs21,1 -n1 -lmt Venus heliacal rising : 2009/03/23 05:30:12.4 LMT (2454913.729310), visible for: 4.9 min swetest -hev2 -p3 -b1.1.2008 -geopos8,47,900 -at1000,10,20,0.15 -obs21,1 -n1 -lmt Venus heliacal setting: 2009/03/25 18:37:41.6 LMT (2454916.276175), visible for: 15.1 min
```

• With good visibility and good eye sight (high Snellen ratio), the "evening first" of the Moon may actually begin in the morning, because the Moon becomes visible before sunset. Note the LMT and duration of visibility in the following example:

```
swetest -hev3 -p1 -b1.4.2008 -geopos8,47,900 -at1000,10,40,0.15 -obs21,1.5 -n1 -lmt
```

Moon evening first: 2008/04/06 10:33:44.3 LMT (2454562.940096), visible for: 530.6 min

- Stars that are circumpolar, but come close to the horizon, may have an evening last and a morning first, but swe\_heliacal\_ut() will not find it. It only works if a star crosses the horizon.
- In high geographic latitudes > 55 (?), unusual things may happen. E.g. Mars can have a morning last appearance. In case the period of visibility lasts for less than 5 days, the function swe\_heliacal\_ut() may miss the morning first.
- With high geographic latitudes heliacal appearances of Mercury and Venus become rarer.

The user must be aware that strange phenomena occur especially for high geographic latitudes and circumpolar objects and that the function swe\_heliacal\_ut() may not always be able to handle them correctly. Special cases can best be researched using the function swe\_vis\_limit\_mag().

swephprg.doc ~ 36 ~

## 7.18. Magnitude limit for visibility: swe\_vis\_limit\_mag()

The function swe\_vis\_limit\_mag() determines the limiting visual magnitude in dark skies. If the visual magnitude mag
of an object is known for a given date (e. g. from a call of function swe\_pheno\_ut(), and if mag is smaller than the value
returned by swe\_vis\_limit\_mag(), then it is visible.

```
double swe_vis_limit_mag(
                         /* Julian day number */
     double tjdut,
     double *dgeo
                         /* geographic position (details under swe heliacal ut() */
                         /* atmospheric conditions (details under swe_heliacal_ut()) */
     double *datm,
                         /* observer description (details under swe heliacal ut()) */
     double *dobs,
                         /* name string of fixed star or planet */
     char *objectname,
                         /* calculation flag, bitmap (details under swe_heliacal_ut()) */
     int32 helflag,
                         /* result: magnitude required of the object to be visible */
     double *dret,
     char * serr);
                         /* error string */
```

#### Function returns:

- -1 on error;
- -2 object is below horizon;
- 0 OK, photopic vision;
- &1 OK, scotopic vision;
- &2 OK, near limit photopic/scotopic vision.

Details for arrays dgeo[], datm[], dobs[] and the other parameters are given under "7.17. Heliacal risings etc.: swe\_heliacal\_ut()".

Details for return array dret[] (array of doubles):

```
dret[0]: limiting visual magnitude (if dret[0] > magnitude of object, then the object is visible);
dret[1]: altitude of object;
dret[2]: azimuth of object;
dret[3]: altitude of sun;
dret[4]: azimuth of sun;
dret[5]: altitude of moon;
dret[6]: azimuth of moon;
dret[7]: magnitude of object.
```

## 7.19. Heliacal details: swe\_heliacal\_pheno\_ut()

The function <code>swe\_heliacal\_pheno\_ut()</code> provides data that are relevant for the calculation of heliacal risings and settings. This function does not provide data of heliacal risings and settings, just some additional data mostly used for test purposes. To calculate heliacal risings and settings, please use the function <code>swe\_heliacal\_ut()</code> documented further above.

```
double swe_heliacal_pheno_ut(
                         /* Julian day number */
     double tjd ut,
                         /* geographic position (details under swe_heliacal_ut() */
     double *dgeo,
     double *datm,
                         /* atmospheric conditions (details under swe_heliacal_ut()) */
                         /* observer description (details under swe_heliacal_ut()) */
     double *dobs,
     char *objectname,
                         /* name string of fixed star or planet */
                         /* event type (details under function swe heliacal ut()) */
     int32 event_type,
                         /* calculation flag, bitmap (details under swe_heliacal_ut()) */
     int32 helflag,
                         /* return array, declare array of 50 doubles */
     double *darr,
     char *serr);
                         /* error string */
```

swephprg.doc ~ 37 ~

## The return array has the following data:

```
[deg]
'0=Alt0
                          topocentric altitude of object (unrefracted)
'1=AppAltO
                          apparent altitude of object (refracted)
               [deg]
'2=GeoAltO
                          geocentric altitude of object
               [deg]
'3=Azi0
               [deg]

## 8. Date and time conversion functions

## 8.1. Calendar date and Julian day: swe\_julday(), swe\_date\_conversion(), /swe\_revjul()

These functions are needed to convert calendar dates to the astronomical time scale which measures time in Julian days.

```
double swe_julday(
     int year,
     int month,
     int day,
     double hour,
     int gregflag);
int swe_date_conversion(
     int y, int m, int d, /* year, month, day */
                          /* hours (decimal, with fraction) */
     double hour,
                          /* calendar 'g'[regorian]|'j'[ulian] */
     char c,
     double *tjd);
                          /* return value for Julian day */
void swe_revjul(
     double tjd,
                          /* Julian day number */
                          /* Gregorian calendar: 1, Julian calendar: 0 */
     int gregflag,
```

swephprg.doc ~ 38 ~

swe\_julday() and swe\_date\_conversion() compute a Julian day number from year, month, day, and hour. swe\_date\_conversion() checks in addition whether the date is legal. It returns OK or ERR.

swe\_revjul() is the reverse function of swe\_julday(). It computes year, month, day and hour from a Julian day number.

The variable gregflag tells the function whether the input date is Julian calendar (gregflag = SE\_JUL\_CAL) or Gregorian calendar (gregflag = SE\_GREG\_CAL).

```
Usually, you will set gregflag = SE_GREG_CAL.
```

The Julian day number has nothing to do with Julius Cesar, who introduced the Julian calendar, but was invented by the monk Julianus. The Julian day number tells for a given date the number of days that have passed since the creation of the world which was then considered to have happened on 1 Jan - 4712 at noon. E.g. the 1.1.1900 corresponds to the Julian day number 2415020.5.

Midnight has always a JD with fraction 0.5, because traditionally the astronomical day started at noon. This was practical because then there was no change of date during a night at the telescope. From this comes also the fact that noon ephemerides were printed before midnight ephemerides were introduced early in the 20th century.

```
8.2. UTC and Julian day: swe_utc_time_zone(), swe_utc_to_jd(), swe_jdet_to_utc(), swe_jdut1_to_utc()
```

The following functions, which were introduced with Swiss Ephemeris version 1.76, do a similar job as the functions described under 7.1. The difference is that input and output times are Coordinated Universal Time (UTC). For transformations between wall clock (or arm wrist) time and Julian Day numbers, these functions are more correct. The difference is below 1 second, though.

Use these functions to convert:

- · local time to UTC and UTC to local time;
- UTC to a Julian day number, and
- a Julian day number to UTC.

Past leap seconds are hard coded in the Swiss Ephemeris. Future leap seconds can be specified in the file seleapsec.txt, see ch. 7.3.

**NOTE**: in case of leap seconds, the input or output time may be 60.9999 seconds. Input or output forms have to allow for this.

```
/* transform local time to UTC or UTC to local time
* input:
* iyear ... dsec date and time
* d_timezone timezone offset
* output:
 iyear_out ... dsec_out
 For time zones east of Greenwich, d_timezone is positive.
 For time zones west of Greenwich, d timezone is negative.
* For conversion from local time to utc, use +d_timezone.
* For conversion from utc to local time, use -d_timezone.
*/
void swe_utc_time_zone(
     int32 iyear, int32 imonth, int32 iday,
     int32 ihour, int32 imin, double dsec,
     double d_timezone,
     int32 *iyear_out, int32 *imonth_out, int32 *iday_out,
     int32 *ihour_out, int32 *imin_out, double *dsec_out);
```

swephprg.doc ~ 39 ~

```
/* input: date and time (wall clock time), calendar flag.
* output: an array of doubles with Julian Day number in ET (TT) and UT (UT1)
* an error message (on error)
* The function returns OK or ERR.
*/
int32 swe_utc_to_jd(
     int32 iyear, int32 imonth, int32 iday,
     int32 ihour, int32 imin, double dsec,
                                                    /* NOTE: second is a decimal */
                          /* Gregorian calendar: 1, Julian calendar: 0 */
     gregflag,
                          /* return array, two doubles:
     dret
                          * dret[0] = Julian day in ET (TT)
                          * dret[1] = Julian day in UT (UT1) */
                          /* error string */
     serr);
/* input: Julian day number in ET (TT), calendar flag
* output: year, month, day, hour, min, sec in UTC */
void swe jdet to utc(
     double tjd et,
                         /* Julian day number in ET (TT) */
                          /* Gregorian calendar: 1, Julian calendar: 0 */
     gregflag,
     int32 *iyear, int32 *imonth, int32 *iday,
     int32 *ihour, int32 *imin, double *dsec);
                                                    /* NOTE: second is a decimal */
/* input: Julian day number in UT (UT1), calendar flag
* output: year, month, day, hour, min, sec in UTC */
void swe_jdut1_to_utc(
     double tjd ut,
                          /* Julian day number in UT (UT1) */
                         /* Gregorian calendar: 1, Julian calendar: 0 */
     gregflag,
     int32 *iyear, int32 *imonth, int32 *iday,
     int32 *ihour, int32 *imin, double *dsec);
                                                    /* NOTE: second is a decimal */
```

## How do I get correct planetary positions, sidereal time, and house cusps, starting from a wall clock date and time?

```
int32 iday, imonth, iyear, ihour, imin, retval;
int32 gregflag = SE GREG CAL;
double d_timezone = 5.5; /* time zone = Indian Standard Time; NOTE: east is positive */
double dsec, tjd_et, tjd_ut;
double dret[2];
char serr[256];
/* if date and time is in time zone different from UTC,
* the time zone offset must be subtracted first in order to get UTC: */
swe utc time zone(iyear, imonth, iday, ihour, imin, dsec, d timezone,
&iyear_utc, &imonth_utc, &iday_utc, &ihour_utc, &imin_utc, &dsec_utc);
/* calculate Julian day number in UT (UT1) and ET (TT) from UTC */
retval = swe_utc_to_jd(iyear_utc, imonth_utc, iday_utc, ihour_utc, imin_utc, dsec_utc, gregflag,
dret, serr);
if (retval == ERR) {
fprintf(stderr, serr); /* error handling */
tjd_et = dret[0]; /* this is ET (TT) */
tjd_ut = dret[1]; /* this is UT (UT1) */
/* calculate planet with tjd et */
swe_calc(tjd_et, ...);
/* calculate houses with tjd_ut */
swe_houses(tjd_ut, ...)
```

swephprg.doc ~ 40 ~

#### And how do you get the date and wall clock time from a Julian day number?

Depending on whether you have tjd\_et (Julian day as ET (TT)) or tjd\_ut (Julian day as UT (UT1)), use one of the two functions swe\_jdet\_to\_utc() or swe\_jdut1\_to\_utc().

```
/* first, we calculate UTC from TT (ET) */

swe_jdet_to_utc(tjd_et, gregflag, &iyear_utc, &imonth_utc, &iday_utc, &ihour_utc, &imin_utc, &dsec_utc);

/* now, UTC to local time (note the negative sign before d_timezone): */

swe_utc_time_zone(iyear_utc, imonth_utc, iday_utc, ihour_utc, imin_utc, dsec_utc, -d_timezone, &iyear, &imonth, &iday, &ihour, &imin, &dsec);
```

## 8.3. Handling of leap seconds and the file seleapsec.txt

The insertion of leap seconds is not known in advance. We will update the Swiss Ephemeris whenever the IERS announces that a leap second will be inserted. However, if the user does not want to wait for our update or does not want to download a new version of the Swiss Ephemeris, he can create a file seleapsec.txt in the ephemeris directory. The file looks as follows (lines with # are only comments):

```
# This file contains the dates of leap seconds to be taken into account
# by the Swiss Ephemeris.
# For each new leap second add the date of its insertion in the format
# yyyymmdd, e.g. "20081231" for 31 december 2008.
# The leap second is inserted at the end of the day.
20081231
```

Before 1972, swe utc to jd() treats its input time as UT1.

**NOTE**: UTC was introduced in 1961. From 1961 - 1971, the length of the UTC second was regularly changed, so that UTC remained very close to UT1.

From 1972 on, input time is treated as UTC.

If delta\_t - nleap - 32.184 > 1, the input time is treated as UT1.

**NOTE**: Like this we avoid errors greater than 1 second in case that the leap seconds table (or the Swiss Ephemeris version) is not updated for a long time.

```
8.4. Mean solar time versus True solar time: swe_time_equ(), swe_lmt_to_lat(), swe_lat_to_lmt()
```

Universal Time (UT or UTC) is based on Mean Solar Time, AKA Local Mean Time, which is a uniform measure of time. A day has always the same length, independent of the time of the year.

In the centuries before mechanical clocks where used, when the reckoning of time was mostly based on sun dials, the True Solar Time was used, also called Local Apparent Time.

The difference between Local Mean Time and Local Apparent Time is called the *equation of time*. This difference can become as large as 20 minutes.

If a historical date was noted in Local Apparent Time, it must first be converted to Local Mean Time by applying the equation of time, before it can be used to compute Universal Time (for the houses) and finally <u>Ephemeris Time</u> (for the planets).

This conversion can be done using the function swe\_lat\_to\_lmt(). The reverse function is swe\_lmt\_to\_lat(). If required, the equation of time itself, i. e. the value e = LAT - LMT, can be calculated using the function swe\_time\_equ():

swephprg.doc ~41 ~

Swiss Ephemeris 2.08 Delta T-related functions

```
double* e,
     char* serr);
For conversions between Local Apparent Time and Local Mean Time, it is recommended to use the following functions:
/* converts Local Mean Time (LMT) to Local Apparent Time (LAT) */
/* tjd lmt and tjd lat are a Julian day number
* geolon is geographic longitude, where eastern longitudes are positive,
* western ones negative */
int32 swe_lmt_to_lat(
     double tjd lmt,
     double geolon,
     double *tjd_lat,
     char *serr);
/* converts Local Apparent Time (LAT) to Local Mean Time (LMT) */
int32 swe lat to lmt(
     double tjd_lat,
     double geolon,
     double *tjd lmt,
     char *serr);
```

## 9. Delta T-related functions

```
/* delta t from Julian day number */
double swe deltat ex(
     double tjd,
     int32 ephe_flag,
     char *serr);
/* delta t from Julian day number */
double swe_deltat(
     double tjd);
/* get tidal acceleration used in swe deltat() */
double swe_get_tid_acc(
     void);
/* set tidal acceleration to be used in swe deltat() */
void swe_set_tid_acc(
     double t_acc);
/* set fixed Delta T value to be returned by swe deltat() */
void swe_set_delta_t_userdef(
     double t_acc);
```

The Julian day number, you compute from a birth date, will be Universal Time (UT, former GMT) and can be used to compute the star time and the houses. However, for the planets and the other factors, you have to convert UT to Ephemeris time (ET):

## 9.1. swe deltat ex()

```
tjde = tjd + swe_deltat_ex(tjd, ephe_flag, serr);
where
tjd = Julian day in UT, tjde = in ET
ephe_flag = ephemeris flag (one of SEFLG_SWIEPH, SEFLG_JPLEPH, SEFLG_MOSEPH)
serr = string pointer for warning messages.
```

If the function is called with SEFLG\_SWIEPH before calling swe\_set\_ephe\_path(), or with or SEFLG\_JPLEPH before calling swe\_set\_jpl\_file(), then the function returns a warning.

swephprg.doc ~ 42 ~

Swiss Ephemeris 2.08 **Delta** T-related functions

The calculation of ephemerides in UT depends on Delta T, which depends on the ephemeris-inherent value of the tidal acceleration of the Moon. The function swe\_deltat\_ex() can provide ephemeris-dependent values of Delta T and is therefore better than the old function swe\_deltat(), which has to make an uncertain guess of what ephemeris is being used. One warning must be made, though:

It is **not recommended** to use a mix of old and new ephemeris files sepl\*.se1, semo\*.se1, seas\*.se1, because the old files were based on JPL Ephemeris DE406, whereas the new ones are based on DE431, and both ephemerides have a different inherent tidal acceleration of the Moon. A mixture of old and new ephemeris files may lead to inconsistent ephemeris output. Using old asteroid files se99999.se1 together with new ones, can be tolerated, though.

## 9.2. swe\_deltat()

```
tjde = tjd + swe_deltat(tjd);
where
tjd = Julian day in UT, tjde = in ET
```

This function is safe only:

- if your software consistently uses the same ephemeris flag;
- if your software consistently uses the same ephemeris files (with SEFLG\_SWIEPH and SEFLG\_MOSEPH);
- if you first call swe set ephe path() (with SEFLG SWIEPH) and swe set jpl file() (with SEFLG JPLEPH).

(Also, it is safe if you first call swe\_set\_tid\_acc() with the tidal acceleration you want. However, please do not use this function unless you really know what you are doing.)

For best control of the values returned, use function swe\_deltat\_ex() instead (see 9.1 above).

The calculation of ephemerides in UT depends on Delta T, which depends on the ephemeris-inherent value of the tidal acceleration of the Moon. In default mode, the function swe\_deltat() automatically tries to find the required values.
Two warnings must be made, though:

- 1. It is **not recommended** to use a mix of old and new ephemeris files sepl\*.se1, semo\*.se1, seas\*.se1, because the old files were based on JPL Ephemeris DE406, whereas the new ones are based on DE431, and both ephemerides have a different inherent tidal acceleration of the Moon. A mixture of old and new ephemeris files may lead to inconsistent ephemeris output. Using old asteroid files se99999.se1 together with new ones, can be tolerated, though.
- 2. The function swe\_deltat() uses a default value of tidal acceleration (that of DE431). However, after calling some older ephemeris, like Moshier ephemeris, DE200, or DE406, swe\_deltat() might provide slightly different values.

In case of troubles related to these two points, it is recommended to:

- either use the function swe\_deltat\_ex();
- or control the value of the tidal acceleration using the functions swe set tid acc() and swe get tid acc().

With Swiss Ephemeris versions until 1.80, this function had **always** to be used, if a nonstandard ephemeris like DE200 or DE421 was used.

Since Swiss Ephemeris version 2.00, this function is usually not needed, because the value is automatically set according to the ephemeris files selected or available. However, under certain circumstances that are described in the section "9.2 swe\_deltat()", the user may want to control the tidal acceleration himself.

To find out the value of the tidal acceleration currently used, call the function

```
acceleration = swe_get_tid_acc();
In order to set a different value, use the function
swe_set_tid_acc(acceleration);
```

The values that acceleration can have are listed in swephexp.h. (e.g. SE\_TIDAL\_200, etc.)

Once the function swe\_set\_tid\_acc() has been used, the automatic setting of tidal acceleration is blocked. In order to unblock it again, call

```
swe_set_tid_acc(SE_TIDAL_AUTOMATIC);
```

swephprg.doc ~ 43 ~

## 9.4. swe set delta t userdef()

This function allows the user to set a fixed Delta T value that will be returned by swe\_deltat() or swe\_deltat\_ex().

The same Delta T value will then be used by swe\_calc\_ut(), eclipse functions, heliacal functions, and all functions that require UT as input time.

In order to return to automatic Delta T, call this function with the following value:

```
swe_set_delta_t_userdef(SE_DELTAT_AUTOMATIC);
```

## 9.5. Future updates of Delta T and the file swe\_deltat.txt

Delta T values for future years can only be estimated. Strictly speaking, the Swiss Ephemeris has to be updated every year after the new Delta T value for the past year has been published by the IERS. We will do our best and hope to update the Swiss Ephemeris every year. However, if the user does not want to wait for our update or does not download a new version of the Swiss Ephemeris he can add new Delta T values in the file swe\_deltat.txt, which has to be located in the Swiss Ephemeris path.

```
# This file allows make new Delta T known to the Swiss Ephemeris.
# Note, these values override the values given in the internal Delta T
# table of the Swiss Ephemeris.
# Format: year and seconds (decimal)
2003 64.47
2004 65.80
2005 66.00
2006 67.00
2007 68.00
2008 68.00
2009 69.00
```

## 10. The function swe\_set\_topo() for topocentric planet positions

This function must be called before topocentric planet positions for a certain birth place can be computed. It tells Swiss Ephemeris, what geographic position is to be used. Geographic longitude geolon and latitude geolat must be in degrees, the altitude above sea must be in meters. Neglecting the altitude can result in an error of about 2 arc seconds with the Moon and at an altitude 3000 m. After calling swe\_set\_topo(), add SEFLG\_TOPOCTR to iflag and call swe\_calc() as with an ordinary computation. E.g.:

```
swe_set_topo(geo_lon, geo_lat, altitude_above_sea);
iflag |= SEFLG_TOPOCTR;
for (i = 0; i < NPLANETS; i++)
{
  iflgret = swe_calc(tjd, ipl, iflag, xp, serr);
  printf("%f\n", xp[0]);
}</pre>
```

The parameters set by swe\_set\_topo() survive swe\_close().

swephprg.doc ~ 44 ~

## 11 Sidereal mode functions

## 11.1. swe\_set\_sid\_mode()

```
void swe set sid mode(int32 sid mode, double t0, double ayan t0);
```

This function can be used to specify the mode for sidereal computations.

swe\_calc() or swe\_fixstar() has then to be called with the bit SEFLG\_SIDEREAL.

If swe set sid mode() is not called, the default ayanamsha (Fagan/Bradley) is used.

If a predefined mode is wanted, the variable sid\_mode has to be set, while t0 and ayan\_t0 are not considered, i.e. can be 0. The predefined sidereal modes are:

```
#define SE SIDM FAGAN BRADLEY
                                            0
#define SE_SIDM_LAHIRI
                                            1
#define SE_SIDM_DELUCE
                                            2
#define SE SIDM RAMAN
                                            3
#define SE SIDM USHASHASHI
                                            4
#define SE SIDM KRISHNAMURTI
                                            5
#define SE_SIDM_DJWHAL_KHUL
                                            6
#define SE SIDM YUKTESHWAR
                                            7
#define SE SIDM JN BHASIN
                                            8
#define SE_SIDM_BABYL_KUGLER1
                                            9
#define SE SIDM BABYL KUGLER2
                                            10
#define SE SIDM BABYL KUGLER3
                                            11
#define SE_SIDM_BABYL_HUBER
                                            12
#define SE SIDM BABYL ETPSC
                                            13
#define SE_SIDM_ALDEBARAN_15TAU
                                            14
#define SE_SIDM_HIPPARCHOS
                                            15
#define SE_SIDM_SASSANIAN
                                            16

For information about the sidereal modes, please read the chapter on sidereal calculations in swisseph.doc.

To define your own sidereal mode, use SE\_SIDM\_USER (=255) and set the reference date (t0) and the initial value of the ayanamsha (ayan\_t0).

```
ayan_t0 = tropical_position_t0 - sidereal_position_t0.
```

Without additional specifications, the traditional method is used. The ayanamsha measured on the ecliptic of t0 is subtracted from tropical positions referred to the ecliptic of date.

**NOTE**: this method will not provide accurate results if you want coordinates referred to the ecliptic of one of the following equinoxes:

Instead, you have to use a correct coordinate transformation as described in the following:

Special uses of the sidereal functions:

a) user-defined ayanamsha with t0 in UT.

If a user-defined ayanamsha is set using SE\_SIDM\_USER, then the t0 is usually considered to be TT (ET). However, t0 can be provided as UT if SE\_SIDM\_USER is combined with SE\_SIDBIT\_USER\_UT.

```
/* with user-defined ayanamsha, t0 is UT */
#define SE_SIDBIT_USER_UT 1024
E.g.:
swe_set_sid_mode(SE_SIDM_USER + SE_SIDBIT_USER_UT, 1720935.589444445, 0);
iflag |= SEFLG_SIDEREAL;
for (i = 0; i < NPLANETS; i++) {
  iflgret = swe_calc(tjd, ipl, iflag, xp, serr);
  printf("%f\n", xp[0]);
}</pre>
```

b) Transformation of ecliptic coordinates to the ecliptic of a particular date. To understand these options, please study them in the General Documentation of the Swiss Ephemeris (swisseph.html, swisseph.pdf).

If a transformation to the **ecliptic of t0** is required the following bit can be added ('ored') to the value of the variable sid\_mode:

```
/* for projection onto ecliptic of t0 */
#define SE_SIDBIT_ECL_T0 256
E.g.:
swe_set_sid_mode(SE_SIDM_J2000 + SE_SIDBIT_ECL_T0, 0, 0);
iflag |= SEFLG_SIDEREAL;
for (i = 0; i < NPLANETS; i++) {
  iflgret = swe_calc(tjd, ipl, iflag, xp, serr);
  printf("%f\n", xp[0]);
}</pre>
```

This procedure is required for the following sidereal modes, i.e. for transformation to the ecliptic of one of the standard equinoxes:

```
#define SE_SIDM_J2000 18
#define SE_SIDM_J1900 19
#define SE_SIDM_B1950 20
```

swephprg.doc ~ 47 ~

If a transformation to the **ecliptic of date** is required the following bit can be added ('ored') to the value of the variable sid\_mode:

c) calculating precession-corrected transits.

The function swe\_set\_sid\_mode() can also be used for calculating "precession-corrected transits". There are two
methods, of which you have to choose the one that is more appropriate for you:

1. If you already have tropical positions of a natal chart, you can proceed as follows:

```
iflgret = swe_calc(tjd_et_natal, SE_ECL_NUT, 0, x, serr);
nut_long_natal = x[2];
swe_set_sid_mode(SE_SIDBIT_USER + SE_SIDBIT_ECL_T0, tjd_et, nut_long_natal);
```

where tjd\_et\_natal is the Julian day of the natal chart (Ephemeris time).

After this calculate the transits, using the function swe\_calc() with the sidereal bit:

```
iflag |= SEFLG_SIDEREAL;
iflgret = swe_calc(tjd_et_transit, ipl_transit, iflag, xpt, serr);
```

2. If you do not have tropical natal positions yet, if you do not need them and are just interested in transit times, you can have it simpler:

```
swe_set_sid_mode(SE_SIDBIT_USER + SE_SIDBIT_ECL_T0, tjd_et, 0);
iflag |= SEFLG_SIDEREAL;
iflgret = swe_calc(tjd_et_natal, ipl_natal, iflag, xp, serr);
iflgret = swe_calc(tjd_et_transit, ipl_transit, iflag, xpt, serr);
```

In this case, the natal positions will be tropical but without nutation. Note that you should not use them for other purposes.

d) solar system rotation plane.

For sidereal positions referred to the solar system rotation plane, use the flag:

```
/* for projection onto solar system rotation plane */
#define SE_SIDBIT_SSY_PLANE 512
```

NOTE: the parameters set by swe\_set\_sid\_mode() survive calls of the function swe\_close().

```
11.2. swe_get_ayanamsa_ex_ut(), swe_get_ayanamsa_ex(), swe_get_ayanamsa() and swe_get_ayanamsa_ut()
```

These functions compute the ayanamsha, i.e. the distance of the tropical vernal point from the sidereal zero point of the zodiac. The ayanamsha is used to compute sidereal planetary positions from tropical ones:

```
pos_sid = pos_trop - ayanamsha
```

Important information concerning the values returned:

- The functions swe\_get\_ayanamsa() and swe\_get\_ayanamsa\_ut() provide the ayanamsha without nutation.
- The functions swe\_get\_ayanamsa\_ex() and swe\_get\_ayanamsa\_ex\_ut() provide the ayanamsha with or without nutation depending on the parameter iflag. If iflag contains (SEFLG\_NONUT) the ayanamsha value is calculated without nutation, otherwise it is calculated including nutation.

It is **not** recommended to use the ayanamsha functions for calculating sidereal planetary positions from tropical positions, since this could lead to complicated confusions. For sidereal planets, please use **swe\_calc\_ut()** and **swe\_calc()** with the flag SEFLG SIDEREAL.

swephprg.doc ~ 48 ~

Use the ayanamsha function only for "academical" purposes, e.g. if you want to indicate the value of the ayanamsha on a horoscope chart. In this case, it is recommended to indicate the ayanamsha including nutation.

Ayanamsha without nutation may be useful in historical research, where the focus usually is on the mere precessional component of the ayanamsha.

Special case of "true" ayanamshas such as "True Chitrapaksha" etc.: The flags SEFLG\_TRUEPOS, SEFLG\_NOABERR and SEFLG\_NOGDEFL can be used here, but users should not do that unless they really understand what they are doing. It means that the same flags are internally used for the calculation of the reference star (e.g. Citra/Spica). Slightly different ayanamsha values will result depending on these flags.

Before calling one of these functions, you have to set the sidereal mode with <a href="mailto:swe\_set\_sid\_mode">swe\_set\_sid\_mode</a>(), unless you want the default sidereal mode, which is the Fagan/Bradley <a href="mailto:ayanamsha">ayanamsha</a>.

```
/* input variables:
* tjd ut = Julian day number in UT
* (tjd_et = Julian day number in ET/TT)
* iflag = ephemeris flag (one of SEFLG SWIEPH, SEFLG JPLEPH, SEFLG MOSEPH)
* plus some other optional SEFLG ...
* output values
* daya = ayanamsha value (pointer to double)
* serr = error message or warning (pointer to string)
* The function returns either the ephemeris flag used or ERR (-1)
int32 swe_get_ayanamsa_ex_ut(
     double tjd_ut,
     int32 iflag,
     double *daya,
     char *serr);
int32 swe get ayanamsa ex(
     double tjd et,
     int32 iflag,
     double *daya,
     char *serr);
double swe get ayanamsa ut(
                          /* input: Julian day number in UT */
     double tjd_ut);
double swe_get_ayanamsa(
     double tid et);
                          /* input: Julian day number in ET/TT */
```

The functions **swe\_get\_ayanamsa\_ex\_ut()** and **swe\_get\_ayanamsa\_ex()** were introduced with Swiss Ephemeris version 2.02, the former expecting input time as UT, the latter as ET/TT.

This functions are **better** than the older functions **swe\_get\_ayanamsa\_ut()** and **swe\_get\_ayanamsa()**.

The function swe\_get\_ayanamsa\_ex\_ut() uses a Delta T consistent with the ephe\_flag specified.

The function swe\_get\_ayanamsa\_ex() does not depend on Delta T; however with fixed-star-based ayanamshas like True Chitrapaksha or True Revati, the fixed star position also depends on the solar ephemeris (annual aberration of the star), which can be calculated with any of the three ephemeris flags.

The differences between the values provided by the new and old functions are **very small** and possibly only relevant for precision fanatics.

The function swe\_get\_ayanamsa\_ut() was introduced with Swisseph Version 1.60 and expects Universal Time instead of Ephemeris Time. (cf. swe\_calc\_ut() and swe\_calc())

## 12. The Ephemeris file related functions (moved to 2.)

Information concerning the functions swe\_set\_ephe\_path(), swe\_close(), swe\_set\_jpl\_file(), and swe\_version() has been moved to chapter 1.

swephprg.doc ~ 49 ~

## 13. The sign of geographical longitudes in Swisseph functions

There is a disagreement between American and European programmers whether eastern or western geographical longitudes ought to be considered positive. Americans prefer to have West longitudes positive, Europeans prefer the older tradition that considers East longitudes as positive and West longitudes as negative.

The Astronomical Almanac still follows the European pattern. It gives the geographical coordinates of observatories in "East longitude".

The Swiss Ephemeris also **follows** the European style. All Swiss Ephemeris functions that use geographical coordinates consider **positive geographical longitudes as East** and **negative ones as West**.

```
E.g. 87w39 = -87.65^{\circ} (Chicago IL/USA) and 8e33 = +8.55^{\circ} (Zurich, Switzerland).
```

There is no such controversy about northern and southern geographical latitudes. North is always positive and south is negative.

## 13.1. Geographic versus geocentric latitude

There is some confusion among astrologers whether they should use geographic latitude (also called geodetic latitude, which is a synonym) or geocentric latitude for house calculations, topocentric positions of planets, eclipses, etc.

Where latitude is an input parameter (or output parameter) in Swiss Ephemeris functions, it is **always** geographic latitude. This is the latitude found in Atlases and Google Earth.

If internally in a function a conversion to geocentric latitude is required (because the 3-d point on the oblate Earth is needed), this is done automatically.

For such conversions, however, the Swiss Ephemeris only uses an ellipsoid for the form of the Earth. It does not use the irregular geoid. This can result in an altitude error of up to 500 meters, or error of the topocentric Moon of up to 0.3 arc seconds.

Astrologers who claim that for computing the ascendant or houses one needs geocentric latitude are wrong. The flattening of the Earth does not play a part in house calculations. Geographic latitude should **always** be used with house calculations.

## 14. House cusp calculation

#### 14.1. swe house name()

#### 14.2. swe houses()

```
/* house cusps, ascendant and MC */
int swe_houses(
                          /* Julian day number, UT */
     double tjd_ut,
                          /* geographic latitude, in degrees */
     double geolat,
     double geolon,
                          /* geographic longitude, in degrees
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
                          /* house method, ascii code of one of the letters documented below */

     double geolon,
```

swephprg.doc ~51~

Swiss Ephemeris 2.08 House cusp calculation

**Note** that all these functions tjd\_ut must be Universal Time.

Also **note** that the array cusps must provide space for **13 doubles** (declare as cusp[13]), otherwise you risk a program crash. With house system 'G' (Gauquelin sector cusps), declare it as cusp[37].

With house system 'G', the cusp numbering is in clockwise direction.

The extended house functions <code>swe\_houses\_ex()</code> and <code>swe\_houses\_ex2()</code> do exactly the same calculations as <code>swe\_houses()</code>. The difference is that the extended functions have a parameter <code>iflag</code>, which can be set to <code>SEFLG\_SIDEREAL</code>, if sidereal house positions are wanted. The house function returns data based on the <code>true</code> equator and equinox of date. If the flag <code>SEFLG\_NONUT</code> is set, then the house cusps will be based on the <code>mean</code> equator and equinox of date. However, we recommend to use the true equator and equinox. The function <code>swe\_houses\_ex2()</code> also provides the speeds ("daily motions") of the house cusps and additional points.

Before calling swe\_houses\_ex() or swe\_houses\_ex() for sidereal house positions, the sidereal mode can be set by calling the function swe\_set\_sid\_mode(). If this is not done, the default sidereal mode, i.e. the Fagan/Bradley ayanamsha, will be used.

The function <code>swe\_houses()</code>, <code>swe\_houses\_ex()</code>, and <code>swe\_houses\_ex2()</code> are most comfortable, as long as houses are to be calculated *for a given date and geographic position*. Sometimes, however, one will need to compute houses *from a given ARMC*, e.g. with the composite horoscope, which has no date, only a composite ARMC which is computed from two natal ARMCs. In this case, the function <code>swe\_houses\_armc()</code> or <code>swe\_houses\_armc\_ex2()</code> can be used. Since these functions require the ecliptic obliquity <code>eps</code>, one will probably want to calculate a composite value for this parameter also. To do this, one has to call <code>swe\_calc()</code> with <code>ipl = SE\_ECL\_NUT</code> for both birth dates and then calculate the average of both <code>eps.</code>

"Sunshine" or Makransky houses require a special handling with the function <a href="mailto:swe\_houses\_armc\_ex2">swe\_houses\_armc\_ex2()</a>. The house system requires as a parameter the declination of the Sun. The user has to calculate the declination of the Sun and save it in the variable ascmc[9]. For house cusps of a composite chart, one has to calculate the composite declination of the Sun (= average of the declinations of the natal Suns).

There is no extended function for swe\_houses\_armc(). Therefore, if one wants to compute such exotic things as the house cusps of a sidereal composite chart, the procedure will be more complicated:

```
/* sidereal composite house computation; with true epsilon, but without nutation in longitude */
swe_calc_ut(tjd_ut1, SE_ECL_NUT, 0, x1, serr);
swe_calc_ut(tjd_ut2, SE_ECL_NUT, 0, x2, serr);
armc1 = swe_sidtime(tjd_ut1) * 15;
armc2 = swe_sidtime(tjd_ut2) * 15;
armc_comp = composite(armc1, armc2); /* this is a function created by the user */
eps_comp = (x1[0] + x2[0]) / 2;
// ayanamsha for the middle of the two birth days.
// alternatively, one could take the mean ayanamsha of the two birth dates.
// the difference will be microscopic.
tjd_comp = (tjd_ut1 + tjd_ut2) / 2;
retval = swe_get_ayanamsa_ex_ut(tjd_comp, iflag, &aya, serr);
swe_houses_armc(armc_comp, geolat, eps_comp, hsys, cusps, ascmc);
for (i = 1; i <= 12; i++)</pre>
```

swephprg.doc ~ 52 ~

Swiss Ephemeris 2.08 House cusp calculation

```
cusp[i] = swe_degnorm(cusp[i] - aya);
for (i = 0; i < 10; i++)
ascmc[i] = swe_degnorm(asc_mc[i] - aya);</pre>
```

Or if you want to calculate sidereal progressions, do as follows:

- calculate the tropical radix\_armc;
- radix armc + direction arc = directed armc;
- use swe houses armc(directed\_armc, ...) or swe houses armc ex2() for the house cusps;
- subtract ayanamsha (swe\_get\_ayanamsa\_ex\_ut()) from the values.

Output and input parameters of the house function:

The first array element <code>cusps[0]</code> is always 0, the twelve houses follow <code>in cusps[1]</code> ... <code>[12]</code>, the reason being that arrays in C begin with the index 0. The indices are therefore:

```
cusps[0] = 0
cusps[1] = house 1
cusps[2] = house 2
```

etc.

In the array ascmc, the function returns the following values:

```
ascmc[0] = Ascendant
ascmc[1] = MC
ascmc[2] = ARMC
ascmc[3] = Vertex
ascmc[4] = "equatorial ascendant"
ascmc[5] = "co-ascendant" (Walter Koch)
ascmc[6] = "co-ascendant" (Michael Munkasey)
ascmc[7] = "polar ascendant" (M. Munkasey)
```

The following defines can be used to find these values:

```
#define SE ASC 0
#define SE_MC 1
#define SE ARMC 2
#define SE VERTEX
                         3
#define SE_EQUASC
                         4
                             /* "equatorial ascendant" */
                         5
                             /* "co-ascendant" (W. Koch) */
#define SE COASC1
                             /* "co-ascendant" (M. Munkasey) */
#define SE COASC2
                         6
#define SE_POLASC
                         7
                              /* "polar ascendant" (M. Munkasey) */
#define SE NASCMC
```

ascmc must be an array of 10 doubles. ascmc[8... 9] are 0 and may be used for additional points in future releases.

The codes **hsys** of the most important house methods are:

```
hsys = 'P' Placidus
'K' Koch
'O' Porphyrius
'R' Regiomontanus
'C' Campanus
'A' or 'E' Equal (cusp 1 is Ascendant)
'W' Whole sign
```

The complete list of house methods in alphabetical order is:

```
hsys = 'B' Alcabitus
'Y' APC houses
'X' Axial rotation system / Meridian system / Zariel
'H' Azimuthal or horizontal system
'C' Campanus
```

Placidus and Koch house cusps as well as Gauquelin sectors **cannot be computed beyond the polar circle**. In such cases, **swe\_houses()** switches to Porphyry houses (each quadrant is divided into three equal parts) and returns the error code ERR. In addition, Sunshine houses may fail, e.g. when required for a date which is outside the time range of our solar ephemeris. Here, also, Porphyry houses will be provided.

The house method codes are actually case sensitive. At the moment, there still are no lowercase house method codes, and if a lowercase code is given to the function, it will be converted to uppercase. However, in future releases, lower case codes may be used for new house methods. In such cases, lower and uppercase won't be equivalent anymore.

The **Vertex** is the point on the ecliptic that is located in precise western direction. The opposition of the **Vertex** is the **Antivertex**, the ecliptic east point.

## 15. House position of a planet: swe\_house\_pos()

To compute the house position of a given body for a given ARMC, you may use:

The variables armc, geolat, eps, and xpin[0] and xpin[1] (ecliptic longitude and latitude of the planet) must be in degrees. serr must, as usually, point to a character array of 256 byte.

The function returns a value between 1.0 and 12.999999, indicating in which house a planet is and how far from its cusp it is.

With house system 'G' (Gauquelin sectors), a value between 1.0 and 36.9999999 is returned. Note that, while all other

swephprg.doc ~ 54 ~

house systems number house cusps in counterclockwise direction, Gauquelin sectors are numbered in clockwise direction.

With Koch houses, the function sometimes returns 0, if the computation was not possible. This happens most often in polar regions, but it can happen at latitudes **below 66°33'** as well, e.g. if a body has a high declination and falls within the circumpolar sky. With circumpolar fixed stars (or asteroids) a Koch house position may be impossible at any geographic location except on the equator.

The user must decide how to deal with this situation.

You can use the house positions returned by this function for house horoscopes (or "mundane" positions). For this, you have to transform it into a value between 0 and 360 degrees. Subtract 1 from the house number and multiply it with 30, or  $\frac{1}{2}$  or  $\frac{1}{2}$  or  $\frac{1}{2}$  30.

You will realize that house positions computed like this, e.g. for the Koch houses, will not agree exactly with the ones that you get applying the Huber "hand calculation" method. If you want a better agreement, set the ecliptic latitude xpin[1] = 0. Remaining differences result from the fact that Huber's hand calculation is a simplification, whereas our computation is geometrically accurate.

Currently, geometrically correct house positions are provided for the following house methods:

```
R Regiomontanus,
P Placidus,
                    K Koch,
                                       C Campanus,
                                                                                 U Krusinski,
A/E Equal,
                    V Vehlow.
                                       W Whole Signs,
                                                           D Equal/MC,
                                                                                 N Equal/Zodiac,
O Porphyry,
                    B Alcabitius,
                                       X Meridian,
                                                           F Carter,
                                                                                 M Morinus,
T Polich/Page,
                    H Horizon,
                                       G Gauquelin.
```

A simplified house position (distance\_from\_cusp / house\_size) is currently provided for the following house methods:

```
Y APC houses, L Pullen SD, O Pullen SR, I Sunshine, S Sripati.
```

This function requires TROPICAL positions in xpin. SIDEREAL house positions are identical to tropical ones in the following cases:

- If the traditional method is used to compute sidereal planets (sid\_pos = trop\_pos ayanamsha). Here the function swe house pos() works for all house systems.
- If a non-traditional method (projection to the ecliptic of t0 or to the solar system rotation plane) is used and the definition of the house system does not depend on the ecliptic. This is the case with Campanus, Regiomontanus, Placidus, Azimuth houses, axial rotation houses. This is **not** the case with equal houses, Porphyry and Koch houses. You have to compute equal and Porphyry house positions on your own. We recommend to avoid Koch houses here. Sidereal Koch houses make no sense with these sidereal algorithms.

## 15.1. Calculating the Gauquelin sector position of a planet with swe\_house\_pos() or swe\_gauquelin\_sector()

For general information on Gauquelin sectors, read chapter 6.5 in documentation file swisseph.doc.

There are two functions that can be used to calculate Gauquelin sectors:

- swe\_house\_pos. Full details about this function are presented in the previous section. To calculate Gauquelin sectors the parameter hsys must be set to 'G' (Gauquelin sectors). This function will then return the sector position as a value between 1.0 and 36.9999999. Note that Gauquelin sectors are numbered in clockwise direction, unlike all other house systems.
- swe\_gauquelin\_sector detailed below.

Function swe\_gauquelin\_sector() is declared as follows:

```
int32 swe gauquelin sector(
     double tjd_ut,
                          /* input time (UT) */
     int32 ipl,
                          /* planet number, if planet, or moon
                          * ipl is ignored if the following parameter (starname) is set */
                          /* star name, if star */
     char *starname,
                          /* flag for ephemeris and SEFLG TOPOCTR */
     int32 iflag,
                          /* method: 0 = with lat., 1 = without lat.,
     int32 imeth,
                          * 2 = from rise/set, 3 = from rise/set with refraction */
                          /* array of three doubles containing
     double *geopos,
                           * geograph. long., lat., height of observer */
```

swephprg.doc ~ 55 ~

This function returns OK or ERR (-1). It returns an error in a number of cases, for example circumpolar bodies with imeth=2. As with other SE functions, if there is an error, an error message is written to serr. dgsect is used to obtain the Gauquelin sector position as a value between 1.0 and 36.9999999. Gauquelin sectors are numbered in clockwise direction.

There are six methods of computing the Gauquelin sector position of a planet:

1. Sector positions from ecliptical longitude AND latitude:

There are two ways of doing this:

- Call <a href="mailto:swe\_house\_pos">swe\_house\_pos</a>() with <a href="https:// https:// https:// https:// swe\_house\_pos</a>() with <a href="https:// https:// https
- Call swe\_gauquelin\_sector() with imeth = 0. This is less efficient than swe\_house\_pos because it recalculates the whole planet whereas swe\_house\_pos() has an input array for ecliptical positions calculated before.
- 2. Sector positions computed from ecliptical longitudes without ecliptical latitudes:

There are two ways of doing this:

- Call swe\_house\_pos() with hsys = 'G', xpin[0] = ecl. longitude of planet, and xpin[1] = 0. This function returns the sector position as a value between 1.0 and 36.9999999.
- Call swe gauquelin sector() with imeth = 1. Again this is less efficient than swe house pos.
- 3. Sector positions of a planet from rising and setting times of planets.

The rising and setting of the disk center is used:

- Call swe\_gauquelin\_sector() with imeth = 2.
- 4. Sector positions of a planet from rising and setting times of planets, taking into account atmospheric refraction.

The rising and setting of the disk center is used:

- Call swe\_gauquelin\_sector() with imeth = 3.
- 5. Sector positions of a planet from rising and setting times of planets.

The rising and setting of the disk edge is used:

- Call swe\_gauquelin\_sector() with imeth = 4.
- 6. Sector positions of a planet from rising and setting times of planets, taking into account atmospheric refraction.

The rising and setting of the disk edge is used:

• Call swe gauquelin sector() with imeth = 5.

## 16. Sidereal time with swe sidtime() and swe sidtime0()

The sidereal time is computed inside the **houses()** function and returned via the variable **armc** which measures sidereal time in degrees. To get sidereal time in hours, divide **armc** by 15.

If the sidereal time is required separately from house calculation, two functions are available. The second version requires obliquity and nutation to be given in the function call, the first function computes them internally. Both return sidereal time at the Greenwich Meridian, measured in hours.

swephprg.doc ~ 56 ~

## 17. Summary of SWISSEPH functions

## 17.1. Calculation of planets and stars

## 17.1.1. Planets, moon, asteroids, lunar nodes, apogees, fictitious bodies

```
long swe_calc_ut(
     double tjd ut,
                          /* Julian day number, Universal Time */
                          /* planet number */
     int ipl,
                          /* flag bits */
     long iflag,
                          /* target address for 6 position values: longitude, latitude, distance,
     double *xx,
     long. speed, lat. speed, dist. speed */
                          /* 256 bytes for error string */
     char *serr);
long swe calc(
                          /* Julian day number, Ephemeris Time */
     double tjd et,
     int ipl,
                          /* planet number */
                          /* flag bits */
     long iflag,
                          /* target address for 6 position values: longitude, latitude, distance,
     double *xx,
     long. speed, lat. speed, dist. speed */
     char *serr);
                          /* 256 bytes for error string */
```

#### 17.1.2. Fixed stars

```
long swe_fixstar_ut(
     char *star,
                          /* star name, returned star name 40 bytes */

int32 swe_lat_to_lmt(
     double tjd lat,
     double geolon,
     double *tjd lmt,
     char *serr);
   17.4. Initialization, setup, and closing functions
```

## 17.4.1. Set directory path of ephemeris files

```
void swe_set_ephe_path(char *path);
/* set name of JPL ephemeris file */
void swe_set_jpl_file(char *fname);
/* close Swiss Ephemeris */
void swe_close(void);
/* find out version number of your Swiss Ephemeris version */
char *swe_version(char *svers);
```

swephprg.doc ~ 64 ~

```
/* svers is a string variable with sufficient space to contain the version number (255 char) */
/* find out the library path of the DLL or executable */
char *swe_get_library_path(char *spath);
/* spath is a string variable with sufficient space to contain the library path (255 char) */
```

#### 17.5. House calculation

#### 17.5.1. Sidereal time

```
double swe_sidtime(double tjd_ut); /* Julian day number, UT */
double swe_sidtime0(
    double tjd_ut, /* Julian day number, UT */
    double eps, /* obliquity of ecliptic, in degrees */
    double nut); /* nutation, in degrees */
```

## 17.5.2. Name of a house method

## 17.5.3. House cusps, ascendant and MC

```
int swe houses(
     double tjd_ut,
                          /* Julian day number, UT */
                          /* geographic latitude, in degrees */
     double geolat,
                          /* geographic longitude, in degrees,
     double geolon,
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
                          /* house method, one of the letters PKRCAV */
     int hsys,
     double* cusps,
                          /* array for 13 doubles */
     double* ascmc);
                          /* array for 10 doubles */
```

## 17.5.4. Extended house function; to compute tropical or sidereal positions

```
int swe_houses_ex(
     double tjd ut,
                          /* Julian day number, UT */
     int32 iflag,
                          /* 0 or SEFLG SIDEREAL or SEFLG RADIANS */
     double geolat,
                          /* geographic latitude, in degrees */
     double geolon,
                          /* geographic longitude, in degrees
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
                          /* house method, one of the letters PKRCAV */
     int hsys,
                          /* array for 13 doubles */
     double* cusps,
                          /* array for 10 doubles */
     double* ascmc);
int swe_houses_ex2(
     double tjd ut,
                          /* Julian day number, UT */
                          /* 0 or SEFLG_SIDEREAL or SEFLG_RADIANS or SEFLG_NONUT */
     int32 iflag,
     double geolat,
                          /* geographic latitude, in degrees */

```

## 17.5.5. Get the house position of a celestial point

```
double swe_house_pos(
                          /* ARMC */
     double armc,
     double geolat,
                          /* geographic latitude, in degrees
                          * eastern longitude is positive,
                          * western longitude is negative,
                          * northern latitude is positive,
                          * southern latitude is negative */
                          /* ecliptic obliquity, in degrees */
     double eps,
                          /* house method, one of the letters PKRCAV */
     int hsys,
     double *xpin,
                          /* array of 2 doubles: ecl. longitude and latitude of the planet */
     char *serr);
                          /* return area for error or warning message */
```

## 17.5.6. Get the Gauquelin sector position for a body

swephprg.doc ~ 66 ~

## 17.6. Auxiliary functions

#### 17.6.1. swe\_cotrans(): coordinate transformation, from ecliptic to equator or vice-versa

# 17.6.2. swe\_cotrans\_sp(): coordinate transformation of position and speed, from ecliptic to equator or vice-versa

#### 17.6.3. swe\_get\_planet\_name(): get the name of a planet

#### 17.6.4. swe\_degnorm(): normalize degrees to the range 0 ... 360

```
double swe_degnorm(double x);
```

#### 17.6.5. swe\_radnorm(): normalize radians to the range 0 ... 2 PI

```
double swe_radnorm(double x);
```

# 17.6.6. swe\_split\_deg(): split degrees to sign/nakshatra, degrees, minutes, seconds of arc

This function takes a decimal degree number as input and provides sign or nakshatra, degree, minutes, seconds and fraction of second. It can also round to seconds, minutes, degrees. For more details see the specifications below.

swephprg.doc ~ 67 ~

```
double swe_split_deg(
     double ddeg,
     int32 roundflag,
     int32 *ideg,
     int32 *imin,
     int32 *isec,
     double *dsecfr,
     int32 *isgn);
/* splitting decimal degrees into (zod. sign,) deg, min, sec. *
* input:
* ddeg decimal degrees, ecliptic longitude
* roundflag by default there is no rounding. if rounding is
* required, the following bits can be set:
# define SE SPLIT DEG ROUND SEC
# define SE_SPLIT_DEG_ROUND_MIN
                                     2
# define SE SPLIT DEG ROUND DEG
# define SE SPLIT DEG ZODIACAL
                                     8
                                          * split into zodiac signs
# define SE_SPLIT_DEG_NAKSHATRA
                                     1024 * split into nakshatras *
# define SE SPLIT DEG KEEP SIGN
                                          * don't round to next zodiac sign/nakshatra,
* e.g. 29.9999998 will be rounded
* to 29°59'59" (or 29°59' or 29°)
* or next nakshatra:
* e.g. 13.3333332 will be rounded
* to 13°19'59" (or 13°19' or 13°)
# define SE SPLIT DEG KEEP DEG
                                     32
                                          * don't round to next degree
* e.g. 10.9999999 will be rounded
* to 10d59'59" (or 10d59' or 10d)
* output:
* ideg degrees,
* imin minutes,
* isec seconds,
* dsecfr fraction of seconds
* isgn zodiac sign number;
* or +/- sign
```

## 17.7. Other functions that may be useful

PLACALC, the predecessor of SWISSEPH, had included several functions that we do not need for SWISSEPH anymore. Nevertheless we include them again in our DLL, because some users of our software may have taken them over and use them in their applications. However, we gave them new names that were more consistent with SWISSEPH.

PLACALC used angular measurements in centiseconds a lot; a centisecond is **1/100** of an arc second. The C type CSEC or centisec is a 32-bit integer. CSEC was used because calculation with integer variables was considerably faster than floating point calculation on most CPUs in 1988, when PLACALC was written.

In the Swiss Ephemeris we have dropped the use of centiseconds and use double (64-bit floating point) for all angular measurements.

#### 17.7.1. Normalize argument into interval [0..DEG360]

```
/ * former function name: csnorm() */
centisec swe_csnorm(centisec p);
```

swephprg.doc ~ 68 ~

Swiss Ephemeris 2.08 The SWISSEPH DLLs

```
Distance in centisecs p1 - p2 normalized to [0..360]
/ * former function name: difcsn() */
centisec swe_difcsn(centisec p1, centisec p2);
               Distance in degrees
/* former function name: difdegn() */
double swe difdegn(double p1, double p2);
       17.7.4. Distance in centisecs p1 - p2 normalized to [-180..180]
/* former function name: difcs2n() */
centisec swe difcs2n(centisec p1, centisec p2);
       17.7.5. Distance in degrees
/* former function name: difdeg2n() */
double swe_difdeg2n(double p1, double p2);
       17.7.6. Round second, but at 29.5959 always down
/* former function name: roundsec() */
centisec swe csroundsec(centisec x);
               Double to long with rounding, no overflow check
/* former function name: d2l() */
long swe_d21(double x);
       17.7.8. Day of week
/* Monday = 0, ... Sunday = 6, former function name: day_of_week() */
int swe day of week(double jd);
       17.7.9. Centiseconds -> time string
/* former function name: TimeString() */
char * swe_cs2timestr(CSEC t, int sep, AS_BOOL suppressZero, char *a);
       17.7.10. Centiseconds -> longitude or latitude string
/* former function name: LonLatString() */
char * swe_cs2lonlatstr(CSEC t, char pchar, char mchar, char *s);
       17.7.11. Centiseconds -> degrees string
/* former function name: DegreeString() */
char * swe_cs2degstr(CSEC t, char *a);
18. The SWISSEPH DLLs
```

There is a 32 bit DLL: swedll32.dll

You can use our programs swetest.c and swewin.c as examples. To compile swetest or swewin with a DLL:

swephprg.doc ~ 69 ~

1. The compiler needs the following files:

```
swetest.c or swewin.c
swedll32.dll
swedll32.lib (if you choose implicit linking)
swephexp.h
swedll.h
sweodef.h
```

2. Define the following macros (-d):

```
USE DLL
```

3. Build swetest.exe from swetest.c and swedll32.lib or swedll64.lib (depending on the 32-bit or 64-bit architecture of your system).

Build swewin.exe from swewin.c, swewin.rc, and swedll32.lib or swedll64.lib.

We provide some project files which we have used to build our test samples. You will need to adjust the project files to your environment.

We have worked with Microsoft Visual C++ 5.0 (32-bit). The DLLs where built with the Microsoft compilers.

## 19. Using the DLL with Visual Basic 5.0

The 32-bit DLL contains the exported function under 'decorated names'. Each function has an underscore before its name, and a suffix of the form @xx where xx is the number of stack bytes used by the call.

The Visual Basic declarations for the DLL functions and for some important flag parameters are in the file \sweph\vb\swedecl.txt and can be inserted directly into a VB program.

A sample VB program vbsweph is included on the distribution, in directory \sweph\vb. To run this sample, the DLL file swedll32.dll must be copied into the vb directory or installed in the Windows system directory.

DLL functions returning a string:

Some DLL functions return a string, e.g.

```
char* swe get planet name(int ipl, char *plname)
```

This function copies its result into the string pointer plname; the calling program must provide sufficient space so that the result string fits into it. As usual in C programming, the function copies the return string into the provided area and returns the pointer to this area as the function value. This allows to use this function directly in a C print statement.

In VB there are three problems with this type of function:

1. The string parameter plname must be initialized to a string of sufficient length before the call; the content does not matter because it is overwritten by the called function. The parameter type must be

```
ByVal plname as String.
```

2. The returned string is terminated by a NULL character. This must be searched in VB and the VB string length must be set accordingly. Our sample program demonstrates how this can be done:

3. The function value itself is a pointer to character. This function value cannot be used in VB because VB does not have a pointer data type. In VB, such a Function can be either declared as type "As long" and the return value ignored, or it can be declared as a Sub. We have chosen to declare all such functions as ,Sub', which automatically ignores the return value.

Declare Sub swe\_get\_planet\_name(ByVal ipl as Long, ByVal plname as String).

swephprg.doc ~ 70 ~

## 20. Using the DLL with Borland Delphi and C++ Builder

#### 20.1. Delphi 2.0 and higher (32-bit)

The information in this section was contributed by Markus Fabian, Bern, Switzerland.

In Delphi 2.0 the declaration of the function swe\_calc() looks like this:

```
xx : Array[0..5] of double;
function swe_calc(
    tjd: double; // Julian day number
    ipl: Integer; // planet number
    iflag: Longint; // flag bits
    var xx[0]: double;
    sErr : PChar // Error-String;
    ): Longint; stdcall; far; external 'swedll32.dll' Name '_swe_calc@24';
```

A nearly complete set of declarations is in file \sweph\delphi2\swe\_d32.pas.

A small sample project for Delphi 2.0 is also included in the same directory (starting with release **1.25** from June 1998). This sample requires the DLL to exist in the same directory as the sample.

#### 20.2. Borland C++ Builder

Borland C++ Builder (BCB) does not understand the Microsoft format in the library file SWEDLL32.LIB; it reports an OMF error when this file is used in a BCB project. The user must create his/her own LIB file for BCB with the utility IMPLIB which is part of BCB.

With the following command you create a special lib file in the current directory:

```
IMPLIB -f -c swe32bor.lib \sweph\bin\swedll32.dll
```

In the C++ Builder project the following settings must be made:

- Menu Options->Projects->Directories/Conditionals: add the conditional define USE DLL;
- Menu Project->Add\_to\_project: add the library file swe32bor.lib to your project;
- In the project source, add the include file "swephexp.h".

In the header file swedll.h the declaration for Dllimport must be

```
#define DllImport extern "C" __declspec(dllimport)
```

This is provided automatically by the <u>\_\_cplusplus</u> switch for release **1.24** and higher. For earlier releases the change must be made manually.

## 21. Using the Swiss Ephemeris with Perl

The Swiss Ephemeris can be run from Perl using the Perl module SwissEph.pm. The module SwissEph.pm uses XSUB ("eXternal SUBroutine"), which calls the Swiss Ephemeris functions either from a C library or a DLL.

In order to run the Swiss Ephemeris from Perl, you have to:

Install the Swiss Ephemeris. Either you download the Swiss Ephemeris DLL from <a href="http://www.astro.com/swisseph">http://www.astro.com/swisseph</a> or you download the Swiss Ephemeris C source code and compile a static or dynamic shared library. We built the package on a Linux system and use a shared library of the Swiss Ephemeris functions.

Install the XS library:

- Unpack the file PerlSwissEph-1.76.00.tar.gz (or whatever newest version there is);
- Open the file Makefile.PL, and edit it according to your requirements. Then run it;
- · make install

If you work on a Windows machine and prefer to use the Swiss Ephemeris DLL, you may want to study Rüdiger Plantiko's Perl module for the Swiss Ephemeris at <a href="http://www.astrotexte.ch/sources/SwissEph.zip">http://www.astrotexte.ch/sources/SwissEph.zip</a>. There is also a documentation in German language by Rüdiger Plantiko at <a href="http://www.astrotexte.ch/sources/swe\_perl.html">http://www.astrotexte.ch/sources/swe\_perl.html</a>).

swephprg.doc ~71~

Swiss Ephemeris 2.08 The C sample program

## 22. The C sample program

The distribution contains executables and C source code of sample programs which demonstrate the use of the Swiss Ephemeris DLL and its functions.

Until version 2.04, all sample programs were compiled with the Microsoft Visual C++ 5.0 compiler (32-bit). Project and Workspace files for these environments are included with the source files.

Since version 2.05, all sample programs and DLLs were compiled on Linux with MinGW. 64-bit programs contain a '64' string in their names.

Since version 2.08, all sample programs and DLLs were compiled with Microsoft Visual Studio 14.0. Again, 64-bit programs contain a '64' in their names.

Directory structure:

Sweph\bin DLL, LIB and EXE file
Sweph\src source files, resource files

sweph\src\swewin32 32-bit windows sample program, uses swedll32.dll

sweph\src\swetest 32-bit character mode sample program sweph\src\swetest64 64-bit character mode sample program

sweph\src\swete32 32-bit character mode sample program, uses swedll32.dll sweph\src\swete64 64-bit character mode sample program, uses swedll64.dll

sweph\src\swedll32.dll 32-bit DLL sweph\src\swedll64.dll 64-bit DLL

sweph\src\swedll32.lib sweph\src\swedll64.lib

You can run the samples in the following environments:

Swetest.exe in Windows command line
Swetest64.exe in Windows command line
Swete32.exe in Windows command line
Swete64.exe in Windows command line

Swewin32.exe in Windows
Character mode executable that needs a DLL

Swete32.exe

The project files for Microsoft Visual C++ are in \sweph\src\swete32.

swetest.c swedll32.lib swephexp.h swedll.h sweodef.h

define macros: USE\_DLL DOS32 DOS\_DEGREE

swewin32.exe

The project files are in \sweph\src\swewin32.

swewin.c swedll32.lib swewin.rc swewin.h swephexp.h swedll.h sweodef.h

resource.h

swephprg.doc ~ 72 ~

Swiss Ephemeris 2.08 The source code distribution

define macro USE DLL.

How the sample programs search for the ephemeris files:

- 1. Check environment variable SE EPHE PATH; if it exists it is used, and if it has invalid content, the program fails.
- 2. Try to find the ephemeris files in the current working directory.
- 3. Try to find the ephemeris files in the directory where the executable resides.
- 4. Try to find a directory named \SWEPH\EPHE in one of the following three drives:
- where the executable resides;
- current drive;
- drive C.

As soon as it succeeds in finding the first ephemeris file it looks for, it expects all required ephemeris files to reside there. This is a feature of the sample programs only, as you can see in our C code.

The DLL itself has a different and simpler mechanism to search for ephemeris files, which is described with the function swe set ephe path() above.

#### 23. The source code distribution

Starting with release **1.26**, the full source code for the Swiss Ephemeris DLL is made available. Users can choose to link the Swiss Ephemeris code directly into their applications. The source code is written in Ansi C and consists of these files:

Bytes	Date	File name	Comment
1639	Nov 28 17:09	Makefile	unix makefile for library
<b>API interface</b>	files		
15050	Nov 27 10:56	swephexp.h	SwissEph API include file

4886	Nov 27 10:06	swephlib.h	
43421	Nov 28 19:33	swetest.c	

In most cases the user will compile a linkable or shared library from the source code, using his favorite C compiler, and then link this library with his application.

If the user programs in C, he will only need to include the header file swephexp.h with his application; this in turn will include sweodef.h. All other source files can be ignored from the perspective of application development.

## 24. The PLACALC compatibility API

(Chapter has been removed.)

Swiss Ephemeris 2.08 Documentation files

#### 25. Documentation files

The following files are in the directory \sweph\doc:

sweph.cdr

sweph.gif

swephin.cdr

swephin.gif

swephprg.doc Documentation for programming, a MS Word-97 file

swephprg.rtf

swisseph.doc General information on Swiss Ephemeris

swisseph.rtf

The files with suffix .CDR are Corel Draw 7.0 documents with the Swiss Ephemeris icons.

## 26. Swisseph with different hardware and compilers

Depending on what hardware and compiler you use, there will be slight differences in your planetary calculations. For positions in longitude, they will be never larger than **0.0001**" in longitude. Speeds show no difference larger than **0.0002** arcsec/day.

The following factors show larger differences between HPUX and Linux on a Pentium II processor:

Mean Node, Mean Apogee:

HPUX PA-Risc non-optimized versus optimized code:

differences are smaller than 0.001 arcsec/day

HPUX PA-Risc versus Intel Pentium gcc non-optimized

differences are smaller than 0.001 arcsec/day

Intel Pentium gss non-optimized versus -O9 optimized:

Mean Node, True node, Mean Apogee: difference smaller than 0.001 arcsec/day

Osculating Apogee: differences smaller than 0.03 arcsec

The differences originate from the fact that the floating point arithmetic in the Pentium is executed with 80 bit precision, whereas stored program variables have only 64 bit precision. When code is optimized, more intermediate results are kept inside the processor registers, i.e. they are not shortened from 80bit to 64 bit. When these results are used for the next calculation, the outcome is then slightly different.

In the computation of speed for the nodes and apogee, differences between positions at close intervals are involved; the subtraction of nearly equal values results shows differences in internal precision more easily than other types of calculations. As these differences have no effect on any imaginable application software and are mostly within the design limit of Swiss Ephemeris, they can be safely ignored.

## 27. Debugging and Tracing Swisseph

## 27.1. If you are using the DLL

Besides the ordinary Swisseph function, there are two additional DLLs that allow you tracing your Swisseph function calls:

Swedlltrs32.dll and swedlltrs64.dll are for single task debugging, i.e. if only one application at a time calls Swisseph functions.

Two output files are written:

- a) swetrace.txt: reports all Swisseph functions that are being called.
- b) swetrace.c: contains C code equivalent to the Swisseph calls that your application did.

The last bracket of the function main() at the end of the file is missing.

If you want to compile the code, you have to add it manually. Note that these files may grow very fast, depending on

swephprg.doc ~ 74 ~

what you are doing in your application. The output is limited to 10000 function calls per run.

Swedlltrm32.dll and swedlltrm64.dll are for multitasking, i.e. if more than one application at a time are calling Swisseph functions. If you used the single task DLL here, all applications would try to write their trace output into the same file. Swedlltrm32.dll and swedlltrm64.dll generate output file names that contain the process identification number of the application by which the DLL is called, e.g. swetrace\_192.c and swetrace\_192.txt.

Keep in mind that every process creates its own output files and with time might fill your disk.

In order to use a trace DLL, you have to replace your Swisseph DLL by it:

- a) save your Swisseph DLL;
- b) rename the trace DLL as your Swisseph DLL (e.g. as swedll32.dll or swedll64.dll).

**IMPORTANT**: The Swisseph DLL will possibly not work properly if called from more than one thread. (**NOTE**: This may not be true any longer for DLLs compiled with MVS version 14.0... (2015); it should be tested again.)

Output samples swetrace.txt:

```
swe deltat: 2451337.870000
                               0.000757
swe_set_ephe_path: path_in =
                               path set = \sweph\ephe\
swe calc: 2451337.870757 -1
                               258 23.437404 23.439365 -0.003530 -0.001961 0.000000

                                                                              -0.000022
     0.000132
swe_get_planet_name: 0
swetrace.c:
#include "sweodef.h"
#include "swephexp.h"
void main()
{
double tjd, t, nut, eps; int i, ipl, retc; long iflag;
double armc, geolat, cusp[12], ascmc[10]; int hsys;
double xx[6]; long iflgret;
char s[AS_MAXCH], star[AS_MAXCH], serr[AS_MAXCH];
/*SWE DELTAT*/
tjd = 2451337.870000000; t = swe_deltat(tjd);
printf("swe_deltat: %f\t%f\t\n", tjd, t);
/*SWE_CALC*/
tjd = 2451337.870757482; ipl = 0; iflag = 258;
iflgret = swe_calc(tjd, ipl, iflag, xx, serr); /* xx = 1239992 */
/*SWE_CLOSE*/
swe close();
```

#### 27.2. If you are using the source code

Similar tracing is also possible if you compile the Swisseph source code into your application. Use the preprocessor definitions TRACE = 1 for single task debugging, and TRACE = 2 for multitasking. In most compilers this flag can be set with - DTRACE = 1 or / DTRACE = 1.

For further explanations, see 21.1.

swephprg.doc ~ 75 ~

## 28. Updates

## 28.1. Updates of documention

Updated	Ву	
30-sep-1997	Alois	added chapter 10 (sample programs)
7-oct-1997	Dieter	inserted chapter 7 (house calculation)
8-oct-1997	Dieter	appendix "Changes from version 1.00 to 1.01"
12-oct-1997	Alois	added new chapter 10 Using the DLL with Visual Basic
26-oct-1997	Alois	improved implementation and documentation of swe_fixstar()
28-oct-1997	Dieter	changes from Version 1.02 to 1.03
29-oct-1997	Alois	added VB sample extension, fixed VB declaration errors
9-nov-1997	Alois	added Delphi declaration sample
8-dec-1997	Dieter	remarks concerning computation of asteroids, changes to version 1.04
8-jan-1998	Dieter	changes from version 1.04 to 1.10.
12-jan-1998	Dieter	changes from version 1.10 to 1.11.
21-jan-1998	Dieter	calculation of topocentric planets and house positions (1.20)
28-jan-1998	Dieter	Delphi 1.0 sample and declarations for 16- and 32-bit Delphi (1.21)
11-feb-1998	Dieter	version 1.23
7-mar-1998	Alois	version 1.24 support for Borland C++ Builder added
4-jun-1998	Alois	version 1.25 sample for Borland Delphi-2 added
29-nov-1998	Alois	version 1.26 source code information added §16, Placalc API added
1-dec-1998	Dieter	chapter 19 and some additions in beginning of Appendix.
2-dec-1998	Alois	equation of time explained (in §4), changes version 1.27 explained
3-dec-1998	Dieter	note on ephemerides of 1992 QB1 and 1996 TL66
17-dec-1998	Alois	note on extended time range of 10'800 years
22-dec-1998	Alois	appendix A
12-jan-1999	Dieter	eclipse functions added, version 1.31
19-apr-1999	Dieter	version 1.4
8-jun-1999	Dieter	chapter 21 on tracing an debugging Swisseph
27-jul-1999	Dieter	info about sidereal calculations
16-aug-1999	Dieter	version 1.51, minor bug fixes
15-feb-2000	Dieter	many things for version 1.60
19-mar-2000	Vic Ogi	swephprg.doc re-edited
17-apr-2002	Dieter	documentation for version 1.64
26-jun-2002	Dieter	version 1.64.01
31-dec-2002	Alois	edited doc to remove references to 16-bit version
12-jun-2003	Alois/Dieter	documentation for version 1.65
10-jul-2003	Dieter	documentation for version 1.66
25-may-2004	Dieter	documentation of eclipse functions updated

## 28.2. Release History

Release	Date	
1.00	30-sep-1997	
1.01	9-oct-1997	houses(), sidtime() made more convenient for developer, Vertex added.
1.02	16-oct-1997	houses() changed again, Visual Basic support, new numbers for fictitious planets This release was pushed to all existing licensees at this date.
1.03	28-oct-1997	minor bug fixes, improved swe_fixstar() functionality. This release was not pushed, as the changes and bug fixes are minor; no changes of function definitions occurred.
1.04	8-dec-1997	minor bug fixes; more asteroids.
1.10	9-jan-1998	bug fix, s. Appendix. This release was pushed to all existing licensees at this date.
1.11	12-jan-1998	small improvements
1.20	20-jan-1998	<b>new</b> : topocentric planets and house positions; a minor bug fix
1.21	28-jan-1998	Delphi declarations and sample for Delphi 1.0
1.22	2-feb-1998	asteroids moved to subdirectory. Swe_calc() finds them there.
1.23	11-feb-1998	two minor bug fixes.
1.24	7-mar-1998	documentation for Borland C++ Builder added, see section 14.3
1.25	4-jun-1998	sample for Borland Delphi-2 added
1.26	29-nov-1998	full source code made available, Placalc API documented

swephprg.doc ~ 77 ~

1.27	2-dec-1998	changes to SE_EPHE_PATH and swe_set_ephe_path()
1.30	17-dec-1998	time range extended to 10'800 years
1.31	12-jan-1999	<mark>new</mark> : Eclipse functions added
1.40	19-apr-1999	new: planetary phenomena added; bug fix in swe_sol_ecl_when_glob();
1.50	27-jul-1999	new: SIDEREAL planetary positions and houses; new fixstars.cat
1.51	16-aug-1999	minor bug fixes
1.60	15-feb-2000	major release with many new features and some minor bug fixes
1.61	11-sep-2000	minor release, additions to se_rise_trans(), swe_houses(), fictitious planets
1.61.01	18-sep-2000	minor release, added Alcabitus house system
1.61.02	10-jul-2001	minor release, fixed bug which prevented asteroid files > 22767 to be accepted
1.61.03	20-jul-2001	minor release, fixed bug which was introduced in 1.61.02: Ecliptic was computed in Radians instead of degrees
1.62.00	23-jul-2001	minor release, several bug fixes, code for fictitious satellites of the Earth, asteroid files > 55535 are accepted
1.62.01	16-oct-2001	bug fix, string overflow in sweph.c::read_const(),
1.63.00	5-jan-2002	added house calculation to swetest.c and swetest.exe
1.64.00	6-mar-2002	house system 'G' for house functions and function swe_gauquelin_sector() for Gauquelin sector calculations
		occultations of planets and fixed stars by the moon
		new Delta T algorithms
1.64.01	26-jun-2002	bug fix in swe_fixstar(). Stars with decl. between -1° and 0° were wrong
1.65.00	12-jun-2003	long variables replaced by INT32 for 64-bit compilers
1.66.00	10-jul-2003	house system 'M' for Morinus houses
1.67.00	31-mar-2005	update Delta T
1.67.01	3-may-2005	docs for sidereal calculations (Chap. 10) updated (precession-corrected transits)
1.70.00	22-feb-2006	all relevant IAU resolutions up to 2005 have been implemented
1.70.01	2-may-2006	minor bug fix
1.70.02	5-may-2006	minor bug fix
1.70.03	30-jun-2006	bug fix
1.71	28-sep-2006	Swiss Ephemeris functions able to calculate minor planet no 134340 Pluto
1.72	28-sep-2007	new function swe_refrac_extended(), Delta T update, minor bug fixes
1.73	29-may-2008	new function swe_fixstars_mag(), Whole Sign houses
1.74	18-jun-2008	bug fixes
1.75	27-aug-2008	Swiss Ephemeris can read newer JPL ephemeris files; bug fixes
1.76	7-apr-2009	heliacal risings, UTC and minor improvements/bug fixes
1.77	26-jan-2010	<pre>swe_deltat(), swe_fixstar() improved, swe_utc_time_zone added</pre>
1.78	3-aug-2012	new precession, improvement of some eclipse functions, some minor bug fixes
1.79	18-apr-2013	new precession, improvement of some eclipse functions, some minor bug fixes
1.80	3-sep-2013	security update, APC houses, bug fixes
2.00	11-feb-2014	Swiss Ephemeris is now based on JPL Ephemeris DE431
2.01	18-mar-2015	udates for tidal acceleration of the Moon with DE431, Delta T, and leap seconds.
		a number of bug fixes
2.02	11-aug-2015	new functions swe_deltat_ex() and
		swe_get_ayanamsha_ex()/swe_get_ayanamsha_ex_ut()
		a number of bug fixes

swephprg.doc ~ 78 ~

2.02.0	)1 14-aug-2015	small corrections to new code, for better backward compatibility
2.03	16-oct-2015	Swiss Ephemeris thread-safe (except DLL)
2.04	21-oct-2015	Swiss Ephemeris DLL based on calling convention _stdcall again, as used to be
2.05	27-may-2015	bug fixes, new ayanamshas, new house methods, osculating elements
2.05.0	)1 27-may-2015	bug fix in new function swe_orbit_max_min_true_distance()
2.06	10-jan-2017	new Delta T calculation
2.07	10-jan-2018	better performance of swe_fixstar() and swe_rise_trans()
2.07.0	01 1-feb-2018	compatibility with Microsoft Visual Studio, minor bugfixes (fixed star functions, leap seconds).
		•
2.08	13-jun-2019	new Delta T and a number of minor bugfixes.
2.09	23-jul-2020	Improved Placidus houses, sidereal ephemerides, planetary magnitudes; minor bug fixes.
2.09.0	)1 23-jul-2020	Bug fix for improved Placidus houses.
2.09.0	2 18-aug-2020	New functions swe_houses_ex2(), swepeeds of house cusps.

## 28.3. Changes from version 2.09.01 to 2.09.02

New functions swe\_houses\_ex2() and swe\_houses\_armc\_ex2() can calculate speeds ("daily motions") of house cusps and related points.

#### 28.4. Changes from version 2.09 to 2.09.01

Bugfix for improved Placidus house cusps near polar circle.

#### 28.5. Changes from version 2.08 to 2.09

This release provides new values for Delta T in 2020 and 2021, an improved calculation of Placidus house cusps near the polar circles, new magnitudes for the major planets, improved sidereal ephemerides, and a few new ayanamshas.

- 1. Our calculation of Placidus house positions did not provide greatest possible precision with high geographic latitudes (noticed by D. Senthilathiban). The
- improvement is documented in the General Documentation under 6.7. "Improvement of the Placidus house calculation in SE 2.09".
- 2. New magnitudes according to Mallama 2018 were implemented. The new values agree with JPL Horizons for all planets except Mars, Saturn, and Uranus.
  - Deviations form Horizons are < 0.1m for Mars, < 0.02m for Saturn and < 0.03m for Uranus.
- 3. New values for Delta T have been added for 2020 and 2021 (the latter estimated).

#### Sidereal astrology:

A lot of work has been done for more correct calculation of ayanamshas.

- 4. Improved general documentation:
  - theory of ayanamsha in general
  - about Lahiri ayanamsha
  - about ayanamsha data in IAE, IENA, RP

These parts of the documentation have been improved considerably. Important contributions were made by D. Senthilathiban and A.K. Kaul.

(Thank you very much, indeed!)

swephprg.doc ~ 79 ~

If questions arise concerning the reproducibility of ayanamsha values as given in IAE, IENA, or Rashtriya Panchang, please study Appendix E

in the general documentation.

5. Small corrections were to some ayanamshas whose original definition was based on an old precession model such as Newcomb or IAU 1976:

ayanamsha	correction	prec. model
0 Fagan-Bradley	0.41256"	Newcomb
1 Lahiri	-0.13036"	IAU 1976
3 Raman	0.82800"	Newcomb
5 Krishnamurti	0.82800"	Newcomb

- 6. Additional, very small, corrections were made with the follwoing ayanamshas:
  - Fagan/Bradley (0): Initial date is Besselian, i.e. 2433282.42346 instead of 2433282.5.
- Lahiri (1): Correction for nutation on initial date was slightly improved in agreement with IAE 1985, namely nutation Wahr (1980) instead of nutation IAU2000B.
  - DeLuce (2): DeLuce assumed zero ayanamsha at 1 Jan. 1 BC, but used Newcomb precession to determine the ayanamsha for current epochs. The ayanamsha

is now based on modern precession. The correction amounts to about 22".

7. New ayanamshas:

- Krishnamurti/Senthilathiban,	SE_SIDM_KRISHNAMURTI_VP291	45
- Lahiri 1940,	SE_SIDM_LAHIRI_1940	43
- Lahiri 1980,	SE_SIDM_LAHIRI_VP285	44
- Lahiri ICRC	SE SIDM LAHIRI ICRC	46

The three additional Lahiri ayanamshas are not really important. They were needed for testing and understanding the history of this aynamasha, and for the same reason they should also be kept. Our hitherto Lahiri ayanamsha (SE\_SIDM\_LAHIRI = 1) is still the official Lahiri ayanamsha as used in Indian Astronomical Ephemeris (IAE) since 1985.

8. Option for ayanamsha calculation relative to ecliptic of date.

```
#define SE_SIDBIT_ECL_DATE 2048
```

With swetest, the option -sidbit2048 can be used. (To be used by those only who understand it.)

#### Other issues:

9. When house calculation fails (which can happen with Placidus, Gauquelin, Koch, Sunshine houses), then the house functions return error but nevertheless provide

Porphyry house cusps. Until now, swetest did so silently, without any warning. It now writes a warning.

- 10. Bug fix in function swehouse.c:swe\_house\_pos(): Corrected double hcusp[36] to double hcusp[37].
- 11. Bug fix in function swe\_refrac\_extended(), calculating true altitude from apparent altitude (SE\_APP\_TO\_TRUE): Function now correctly returns true altitude if apparent

altitude is greater or equal to the dip of the horizon.

12. Bug fix in function swe\_get\_planet\_name() when used for asteroids. If the file s\*.se1 was older than 2005, then the function provided a name string beginning

with "? ".

13. Behaviour of occultation functions with fixed stars: attr[0] and attr[2] (fraction of diameter or disk occulted by the Moon) now have the value 1 (in previous versions

they had value 100). The new value is consistent with those given with occultations of planetary disks.

- 14. The function swecalc() near its beginning set serr = " in versions up to 2.08. This destroyed possible warnings written into it in the calling function swe\_calc().
  - 15. Perl-Swisseph:
    - Functions swe\_sol\_eclipse\_where(), swe\_sol\_eclipse\_how(),
    - swe\_lun\_eclipse\_how() now provide Saros numbers, in the array attr as well as in the variables saros\_series and saros\_no.
    - Functions swe\_lun\_eclipse\_when() now also provide start and end times ecl\_begin und ecl\_end (as with sol\_eclipse\_when\_glob()).

swephprg.doc ~ 80 ~

### 28.6. Changes from version 2.07.01 to 2.08

This release provides a number minor bug fixes and cleanups, an update for current Delta T, a few little improvements of swetest and three new ayanamshas.

#### Fixed star functions:

• Wrong distance values in the remote past or future were corrected.

Position values were not affected by this bug.

• Inaccurate speed values of fixed star functions were corrected.

The nutation component was missing.

- When sepl\*/semo\* are not installed, swe\_fixstar2() now defaults to the Moshier ephemeris. With version 2.07\*, it has returned error.
- Repeated call of swe\_fixstar\_mag() did not work correctly with SE 2.07\*. Now it does.
- The AU constant has been updated to the current IAU standard. This change does not have any noticeable effect on planetary or star positions.

#### Ayanamshas:

• New ayanamshas were added:

SE\_SIDM\_GALCENT\_COCHRANE (David Cochrane)

SE\_SIDM\_GALEQU\_FIORENZA (Nick Anthony Fiorenza)

SE\_SIDM\_VALENS\_MOON (Vettius Valens, 2nd century CE)

For information on these, please look them up in the general documentation of the Swiss Ephemeris.

• Kugler ayanamshas were corrected:

E = -3;22 in source corresponds ayanamsha ay = 5;40

E = -4;46 in source corresponds ayanamsha ay = 4;16

E = -5;37 in source corresponds ayanamsha ay = 3;25

(Nobody has noticed this error for 20 years.)

#### Other stuff:

- swe\_houses\_ex() now also understands iflag & SEFLG\_NONUT. This could be relevant for the calculation of sidereal house cusps.
- swe\_pheno() and swe\_pheno\_ut(): the functions now return the correct ephemeris flag.
- swe split deg() has had a problem if called with

SE\_SPLIT\_DEG\_ROUND\_SEC or SE\_SPLIT\_DEG\_ZODIACAL:

Sometimes, it provided sign number 12 when a position was rounded to 360°. This was wrong because sign numbers are defined as 0 - 11. This is a very old bug. From now on, only sign numbers 0 - 11 can occur.

A similar error occurred with SE\_SPLIT\_DEG\_ROUND\_SEC and SE\_SPLIT\_DEG\_NAKSHATRA, where only nakshatra numbers 0 - 26 should be returned, no 27.

Macros EXP16, USE\_DLL16 und MAKE\_DLL16 for very old compilers were removed.

#### Improvements of swetest:

- With calculations depending on geographic positions such as risings and local eclipses, an output line indicating the geographic position has been added. Those who use swetest system calls in their software (which we actually do not recommend) should test if this does not create.
- The output header of swetest now shows both true and mean epsilon.
- swetest option -sidudef[jd,ay0,...] allows user-defined ayanamsha. For detailed info about this option call swetest -h.

All new DLLs and executables were created with Microsoft Visual Studio 2015 (version 14.), no longer with MinGW on Linux. The usage of MinGW since Swiss Ephemeris version 2.05 had caused difficult problems for some of our users. We hope that these problems will now disappear.

## 28.7. Changes from version 2.07 to 2.07.01

Changes for compatibility with Microsoft Visual C. Affected functions are: swe fixstar2(), swe fixstar2 ut(),

swe\_fixstar2\_mag().

• Minor bugfixes in the functions swe\_fixstar\_ut(), swe\_fixstar2\_ut() and swe\_fixstar2(). In particular, calls of the \_ut functions with sequential star numbers did not work properly. This was an older bug, introduced with version 2.02.01 (where it appeared in function swe\_fixstar\_ut()).

Wrong leap second (20171231) removed from swedate.c. Affected functions were: swe\_utc\_to\_jd(), swe\_jdet\_to\_utc(), swe\_jdut1\_to\_utc().

## 28.8. Changes from version 2.06 to 2.07

- Greatly enhanced performance of swe\_rise\_trans() with calculations of risings and settings of planets except for high geographic latitudes.
- New functions swe\_fixstar2(), swe\_fixstar2\_ut(), and swe\_fixstar2\_mag() with greatly increased performance. Important additional remarks are given further below.
- Fixed stars data file sefstars.txt was updated with new data from SIMBAD database.
- swe\_fixstar(): Distances (in AU) and daily motions of the stars have been added to the return array. The daily motions
  contain components of precession, nutation, aberration, parallax and the proper motions of the stars. The usage of
  correct fixed star distances leads to small changes in fixed star positions and calculations of occultations of stars by
  the Moon (in particular swe\_lun\_occult\_when\_glob()).

To transform the distances from AU into lightyears or parsec, please use the following defines, which are in swephexp.h: #define AUNIT TO LIGHTYEAR (1.0/63241.077088071)

#define AUNIT\_TO\_PARSEC (1.0/206264.8062471)

- There was a bug with daily motions of planets in sidereal mode: They contained precession! (Nobody ever noticed or complained for almost 20 years!)
- In JPL Horizons mode, the Swiss Ephemeris now reproduces apparent position as provided by JPL Horizons with an accuracy of a few milliseconds of arc for its *whole time range*. Until SE 2.06 this has been possible only after 1800. Please note, this applies to JPL Horizons mode only (SEFLG\_JPLHOR and SEFLG\_JPLHOR\_APPROX together with an original JPL ephemeris file; or swetest -jplhor, swetest -jplhora). Our default astronomical methods are those of IERS Conventions 2010 and Astronomical Almanac, *not* those of JPL Horizons.
- After consulting with sidereal astrologers, we have changed the behavior of the function swe\_get\_ayanamsa\_ex(). See
  programmer's documentation swephprg.htm, chap. 10.2. Note this change has no impact on the calculation of
  planetary positions, as long as you calculate them using the sidereal flag SEFLG\_SIDEREAL.
- New ayanamsha added:

"Vedic" ayanamsha according to Sunil Sheoran (SE\_SIDM\_TRUE\_SHEORAN)

It must be noted that in Sheoran's opinion 0 Aries = 3°20' Ashvini. The user has to carry the responsibility to correctly handle this problem. For calculating a planet's nakshatra position correctly, we recommend the use of the function swe\_split\_deg() with parameter roundflag |= SE\_SPLIT\_DEG\_NAKSHATRA or roundflag |= 1024. This will handle Sheoran's ayanamsha correctly.

For more information about this and other ayanamshas, I refer to the general documentation chap. 2.7 or my article on ayanamshas here: <a href="https://www.astro.com/astrology/in ayanamsha">https://www.astro.com/astrology/in ayanamsha</a> e.htm

• Function swe\_rise\_trans() has two new flags:

SE\_BIT\_GEOCTR\_NO\_ECL\_LAT 128 /\* use geocentric (rather than topocentric) position of object and ignore its ecliptic latitude \*/

SE\_BIT\_HINDU\_RISING /\* calculate risings according to Hindu astrology \*/

- Of course, as usual, leap seconds and Delta T have been updated.
- Calculation of heliacal risings using swe\_heliacal\_ut() now also works with Bayer designations, with an initial comma, e.g. ",alTau".
- Problem left undone:

Janez Križaj noticed that in the remote past the ephemeris of the Sun has some unusual ecliptic latitude, which amounts to +-51 arcsec for the year -12998. This phenomenon is due to an intrinsic inaccuracy of the precession theory Vondrak 2011 and therefore we do not try to fix it. While the problem could be avoided by using some older precession theory such as Laskar 1986 or Owen 1990, we give preference to Vondrak 2011 because it is in very good agreement with precession IAU2006 for recent centuries. Also, the "problem" (a very small one) appears only in the very remote past,

swephprg.doc ~82 ~

not in historical epochs.

Important additional information on the new function swe\_fixstar2() and its derivatives with increased performance:

Some users had criticized that swe\_fixstar() was very inefficient because it reopened and scanned the file sefstars.txt for each fixed star to be calculated. With version 2.07, the new function swe\_fixstar2() reads the whole file the first time it is called and saves all stars in a sorted array of structs. Stars are searched in this list using the binary search function bsearch(). After a call of swe\_close() the data will be lost. A new call of swe\_fixstar2() will reload all stars from sefstars.txt.

The declaration of swe fixstar2() is identical to old swe fixstar(), but its behavior is slightly different:

Fixed stars can be searched by

- full traditional name
- Bayer/Flamsteed designation
- traditional name with wildcard character '%'

(With previous versions, search string "aldeb" provided the star Aldebaran. This does not work anymore. For abbreviated search strings, a '%' wildcard must, be added, e.g. "aldeb%".)

With the old swe\_fixstar(), it was possible to use numbers as search keys. The function then returned the n-th star it found in the list. This functionality is still available in the new version of the function, but the star numbering does no longer follow the order of the stars in the file, but the order of the sorted Bayer designations. Nevertheless this feature is very practical if one wants to create a list of all stars.

```
for i=1; i<10000; i++) { // choose any number greater than number of lines (stars) in file
sprintf(star, "%d", i);
returncode = swe_fixstar2(star, tjd, ...);
... whatever you want to do with the star positions ...
if (returncode == ERR)
break;
}</pre>
```

#### 28.9. Changes from version 2.05.01 to 2.06

New calculation of Delta T, according to:

Stephenson, F.R., Morrison, L.V., and Hohenkerk, C.Y., "Measurement of the Earth's Rotation: 720 BC to AD 2015", published by Royal Society Proceedings A and available from their website at

http://rspa.royalsocietypublishing.org/content/472/2196/20160404

http://astro.ukho.gov.uk/nao/lvm/

http://astro.ukho.gov.uk/nao/lvm/Table-S15.txt

This publication provides algorithms for Delta T from 721 BCE to 2016 CE based on historical observations of eclipses and occultations, as well as a parabolic function for epochs beyond this time range.

The new Swiss Ephemeris uses these algorithms before 1 Dec. 1955 and then switches over to values provided by Astronomical Almanac 1986(etc.) pp. K8-K9 and values from IERS.

Delta T values from 1973 to today have been updated by values from IERS, with four-digit accuracy. Two small bugs that interpolates these tabulated data have been fixed. Changes in Delta T within this time range are smaller than 5 millisec. The accuracy possible with 1-year step width is about 0.05 sec. For better accuracy, we would have to implement a table of monthly or daily delta t values.

Time conversions from or to UTC take into account the leap second of 31 Dec 2016.

Minor bug fixes in heliacal functions. E.g., heliacal functions now work with ObjectName in uppercase or lowercase.

Function swe\_house\_pos() now provides geometrically correct planetary house positions also for the house methods I, Y, S (Sunshine, APC, Scripati).

House method N ( $1 = 0^{\circ}$  Widder) did not work properly with some sidereal zodiac options.

swe\_houses\_ex() with sidereal flag and rarely used flags SE\_SIDBIT\_ECL\_T0 or SE\_SIDBIT\_SSY\_PLANE returned a wrong ARMC.

Better behavior of swetest -rise in polar regions.

swetest understands a new parameter -utcHH:MM:SS, where input time is understood as UTC (whereas -utHH:MM:SS

swephprg.doc ~ 83 ~

understands it as UT1). Note: Output of dates is always in UT1.

About 110 fixed stars were added to file sefstars.txt.

#### 28.10. Changes from version 2.05 to 2.05.01

Bug in new function **swe\_orbit\_max\_min\_true\_distance()** has been fixed.

#### 28.11. Changes from version 2.04 to 2.05

Starting with release 2.05, the special unit test system **setest** designed and developed by Rüdiger Plantiko is used by the developers. This improves the reliability of the code considerably and has led to the discovery of multiple bugs and inconsistencies.

Note: **setest** is not to be confused with **swetest**, the test command-line utility program.

Bug fixes and new features:

- 1) The **Fixed stars file sefstars.txt** was updated with new data from the Simbad Database. Some errors in the file were fixed.
- **2) Topocentric positions** of planets: The value of speed was not very good. This problem was found by Igor "TomCat" Germanenko in March 2015. A more accurate calculation of speed from three positions has now been implemented.

In addition, topocentric positions had an error < 1 arcsec if the function swe\_calc() was called without SEFLG\_SPEED. This problem was found by Bernd Müller and has now been fixed.

**3) Initial calls of the Swiss Ephemeris**: Some problems were fixed which appeared when users did calculations without opening the Swiss, i.e. without calling the function **swe\_set\_ephe\_path**().

**NOTE**: It is still strongly recommended to call this function in the beginning of an application in order to make sure that the results are always consistent.

**4) New function swe\_get\_orbital\_elements()** calculates osculating Kepler elements and some other data for planets, Earth-Moon barycentre, Moon, and asteroids. The program swetest has a new option -orbel that displays these data.

New function **swe\_orbit\_max\_min\_true\_distance()** provides maximum, minimum, and true distance of a planet, on the basis of its osculating ellipse. The program swetest, when called with the option -fq, displays a relative distance of a planet (0 is maximum distance, 1000 is minimum distance).

- 5) New house methods were added:
- F Carter poli-equatorial house system
- D Equal houses, where cusp 10 = MC
- I Sunshine
- N Equal houses, where cusp 1 = 0 Aries
- L Pullen SD (sinusoidal delta) = ex Neo-Porphyry
- Q Pullen SR (sinusoidal ratio)
- S Sripati

#### Note:

- Sunshine houses require some special handling with the functions swe\_houses\_armc() and swe\_house\_pos().
   Detailed instructions are given in the Programmer's Manual.
- Until version 2.04, the function swe\_house\_pos() has provided Placidus positions for the APC method. From version
  2.05 on, it provides APC positions, but using a simplified method, namely the position relative to the house cusp and
  the house size. This is not really in agreement with the geometry of the house system.
- The same simplified algorithm has been implemented for the following house methods:

Y APC, I Sunshine, L Pullen SD, Q Pullen SR, S Sripati

We hope to implement correct geometrical algorithms with time.

Minor bugfixes with houses:

- APC houses had nan (not a number) values at geographic latitude 0.
- APC houses had inaccurate MC/IC at geographic latitude 90.
- Krusinski houses had wrong (opposite) house positions with function swe\_house\_pos() at geographic latitude 0.0.

swephprg.doc ~84 ~

6) Sidereal zodiac defined relative to UT or TT:

A problem found by Parashara Kumar with the ayanamsha functions: The function swe\_get\_ayanamsa() requires TT (ET), but some of the ayanamshas were internally defined relative to UT. Resulting error in ayanamsha were about 0.01 arcsec in 500 CE. The error for current dates is about 0.0001 arcsec.

The internal definitions of the ayanamshas has been changed and can be based either on UT or on TT.

Nothing changes for the user, except with user-defined ayanamshas. The t0 used in swe\_set\_sid\_mode() is considered to be TT, except if the new bit flag SE\_SIDBIT\_USER\_UT (1024) is or'ed to the parameter sid\_mode.

- 7) Ayanamshas: Some ayanamshas were corrected:
- The "True Revati Ayanamsha" (No. 28) (had the star at 0 Aries instead of 29°50' Pisces.
- The Huber Babylonian ayanamsha (No. 12) has been wrong for many years by 6 arc min. This error was caused by wrong information in a publication by R. Mercier. The correction was made according to Huber's original publication. More information is given in the General Documentation of the Swiss Ephemeris.
- Ayanamsha having Galactic Centre at 0 Sagittarius (No. 17) has been changed to a "true" ayanamsha that has the GC always at 0 Sag.

In addition, the following ayanamshas have been added:

- Galactic ayanamsha (Gil Brand) SE\_SIDM\_GALCENT\_RGBRAND
- Galactic alignment (Skydram/Mardyks) SE\_SIDM\_GALALIGN\_MARDYKS
- Galactic equator (IAU 1958) SE\_SIDM\_GALEQU\_IAU1958
- Galactic equator true/modern SE\_SIDM\_GALEQU\_TRUE
- Galactic equator in middle of Mula SE\_SIDM\_GALEQU\_MULA
- True Mula ayanamsha (Chandra Hari) SE\_SIDM\_TRUE\_MULA
- Galactic centre middle Mula (Wilhelm) SE\_SIDM\_GALCENT\_MULA\_WILHELM
- Aryabhata 522 SE\_SIDM\_ARYABHATA\_522
- Babylonian Britton SE\_SIDM\_BABYL\_BRITTON

More information about these ayanamshas is given in the General Documentation of the Swiss Ephemeris.

**8)** \_**TRUE**\_ ayanamshas algorithm (True Chitra, True Revati, True Pushya, True Mula, Galactic/Gil Brand, Galactic/Wilhelm) always keep the intended longitude, with or without the following iflags: SEFLG\_TRUEPOS, SEFLG\_NOABERR, SEFLG\_NOGDEFL.

So far, the True Chitra ayanamsha had Spica/Chitra at 180° exactly if the *apparent* position of the star was calculated, however not if the *true* position (without aberration/light deflection) was calculated. However, some people may find it more natural if the star's true position is exactly at 180°.

- 9) Occultation function swe\_lun\_occult\_when\_loc():
- Function did not correctly detect daytime occurrence with partial occultations (a rare phenomenon).
- Some rare occultation events were missed by the function.

As a result of the changes three are very small changes in the timings of the events.

- Occultation of fixed stars have provided four contacts instead of two. Now there are only two contacts.
- 10) Magnitudes for Venus and Mercury have been improved according to Hilten 2005.

The Swiss Ephemeris now provides the same magnitudes as JPL's Horizons System.

- **11) Heliacal functions**: A few bugs discovered by Victor Reijs have been fixed, which however did not become apparent very often.
- **12) User-defined Delta T**: For archeoastronomy (as suggested by Victor Reijs) a new function swe\_set\_delta\_t\_userdef() was created that allows the user to set a particular value for delta t.
- 13) Function swe\_nod\_aps(): a bug was fixed that occurred with calculations for the EMB.
- **14) New function swe\_get\_library\_path**(): The function returns the path in which the executable resides. If it is running with a DLL, then returns the path of the DLL.

#### 28.12. Changes from version 2.03 to 2.04

**The DLL of version 2.03 is not compatible with existing software.** In all past versions, the function names in the DLL were "decorated" (i.e. they had an initial '\_' and a final '@99'). However, version 2.03 had the function names

swephprg.doc ~85 ~

"undecorated". This was a result of the removal of the PASCAL keyword from the function declarations. Because of this, the DLL was created with the \_\_cdecl calling convention whereas with the PASCAL keyword it had been created with the \_\_stdcall calling convention.

Since VBA requires \_stdcall, we return to \_stdcall and to decorated function names.

The macro PASCAL\_CONV, which had been misleading, was renamed as CALL\_CONV.

#### 28.13. Changes from version 2.02.01 to 2.03

This is a minor release, mainly for those who wish a thread-safe Swiss Ephemeris. It was implemented according to the suggestions made by Rüdiger Plantico and Skylendar. Any errors might be Dieter Koch's fault. On our Linux system, at least, it seems to work.

However, it seems that that we cannot build a thread-safe DLL inhouse at the moment. If a group member could provide a thread-safe DLL, that could be added to the Swiss Ephemeris download area.

Other changes:

FAR, PASCAL, and EXP16 macros in function declarations were removed.

Minor bug fixes:

- swe\_calc\_ut(): With some nonsensical SEFLG\_ combinations, such as a combination of several ephemeris flags, slightly inconsistent results were returned.
- swe\_calc(planet) with SEFLG\_JPLEPH: If the function was called with a JD beyond the ephemeris range, then a subsequent call of swe\_calc(SE\_SUN) for a valid JD would have provided wrong result. This was a very old bug, found by Anner van Hardenbroek.

Note, other issues that have been discussed recently or even longer ago had to be postponed.

#### 28.14. Changes from version 2.02 to 2.02.01

• For better backward-compatibility with 2.0x, the behavior of the old Delta T function swe\_deltat() has been modified as follows:

swe\_deltat() assumes

SEFLG\_JPLEPH, if a JPL file is open;

SEFLG SWIEPH, otherwise.

Usually, this modification does not result in values different from those provided by former versions SE 2.00 and 2.01.

Note, SEFLG\_MOSEPH is never assumed by swe\_deltat(). For consistent handling of ephemeris-dependent Delta T, please use the new Delta T function swe\_deltat\_ex(). Or if you understand the lunar tidal acceleration problem, you can use swe\_set\_tid\_acc() to define the value you want.

- With version 2.02, software that does not use swe\_set\_ephe\_path() or swe\_set\_jpl\_file() to initialize the Swiss Ephemeris may fail to calculate topocentric planets with swe\_calc() or swe\_calc\_ut() (return value ERR). Version 2.02.01 is more tolerant again.
- Ayanamshas TRUE\_REVATI, TRUE\_PUSHYA now also work if not fixed stars file is found in the ephemeris path. With TRUE\_CHITRA, this has been the case for longer.
- Bug fixed: since version 2.00, the sidereal modes TRUE\_CHITRA, TRUE\_REVATI, TRUE\_PUSHYA provided wrong latitude and speed for the Sun.

Thanks to Thomas Mack for some contributions to this release.

## 28.15. Changes from version 2.01 to 2.02

Many thanks to all who have contributed bug reports, in particular Thomas Mack, Bernd Müller, and Anner van Hardenbroek.

Swiss Ephemeris 2.02 contains the following updates:

• A bug was fixed in sidereal time functions before 1850 and after 2050. The bug was a side effect of some other bug fix in Version 2.01. The error was smaller than 5 arc min for the whole time range of the ephemeris.

The bug also resulted in errors of similar size in azimuth calculations before 1850 and after 2050.

swephprg.doc ~ 86 ~

Moreover, the bug resulted in errors of a few milliarcseconds in topocentric planetary positions before 1850 and after 2050

In addition, the timings of risings, settings, and local eclipses may be slightly affected, again only before 1850 and after 2050.

- A bug was fixed that sometimes resulted in a program crash when function calls with different ephemeris flags (SEFLG\_JPLEPH, SEFLG\_SWIEPH, and SEFLG\_MOSEPH) were made in sequence.
- Delta T functions:
- New function swe\_deltat\_ex(tjd\_ut, ephe\_flag, serr), where ephe\_flag is one of the following:

SEFLG\_SWIEPH, SEFLG\_JPLEPH, SEFLG\_MOSEPH, and serr the usual string for error messages.

It is wise to use this new function instead of the old swe\_deltat(), especially if one uses more than one ephemeris or wants to compare different ephemerides in UT.

Detailed explanations about this point are given further below in the general remark concerning Swiss Ephemeris 2.02 and above in chap. 8 (on Delta T functions).

• The old function swe\_deltat() was slightly modified. It now assumes

SEFLG\_JPLEPH, if a JPL file is open;

SEFLG\_SWIEPH, if a Swiss Ephemeris sepl\* or semo\* file is found;

SEFLG\_MOSEPH otherwise.

Usually, this modification does not result in values different from those provided by former versions SE 2.00 and 2.01.

- Ayanamsha functions:
- New functions swe\_get\_ayanamsa\_ex(), swe\_get\_ayanamsa\_ex\_ut() had to be introduced for similar reasons as swe\_deltat\_ex(). However, differences are very small, especially for recent dates.

For detailed explanations about this point, see general remarks further below.

The old function swe\_get\_ayanamsa() was modified in a similar way as swe\_deltat().

Usually, this modification does not result in different results.

- Eclipse and occultation functions:
- Searches for non-existing events looped through the whole ephemeris.

With version 2.02, an error is returned instead.

- Simplified (less confusing) handling of search flag in functions swe\_sol\_eclipse\_when\_glob() and swe\_lun\_occult\_when\_glob() (of course backward compatible).
- fixed bug: swe\_lun\_occult\_when\_loc() has overlooked some eclipses in polar regions (bug introduced in Swiss Ephemeris 2.01)
- SEFLG\_JPLHOR also works in combination with SEFLG\_TOPOCTR

#### swetest:

- The parameter -at(pressure), (temperature) can also be used with calculation of risings and altitudes of planets.
- Some rounding errors in output were corrected.
- swemptab.c was renamed swemptab.h.
- Small correction with SEFLG\_MOSEPH: frame bias was not correctly handled so far. Planetary positions change by less than 0.01 arcsec, which is far less than the inaccuracy of the Moshier ephemeris.

A general remark concerning Swiss Ephemeris 2.02:

Since Swiss Ephemeris 2.0, which can handle a wide variety of JPL ephemerides, old design deficiencies of some functions, in particular swe\_deltat(), have become incommoding under certain circumstances. Problems may (although need not) have occurred when the user called swe\_calc\_ut() or swe\_fixstar\_ut() for the remote past or future or compared planetary positions calculated with different ephemeris flags (SEFLG\_SWIEPH, SEFLG\_JPLEPH, SEFLG\_MOSEPH).

The problem is that the Delta T function actually needs to know what ephemeris is being used but does not have an input parameter ephemeris\_flag. Since Swiss Ephemeris 2.00, the function swe\_deltat() has therefore made a reasonable guess what kind of ephemeris was being used, depending on the last call of the function swe\_set\_ephe\_path(). However, such guesses are not necessarily always correct, and the functions may have returned slightly inconsistent return values, depending on previous calculations made by the user. Although the resulting error will be always smaller than the inherent inaccuracy in historical observations, the design of the function swe\_deltat() is obviously inappropriate.

A similar problem exists for the function swe\_get\_ayanamsa() although the possible inconsistencies are very small.

To remedy these problems, Swiss Ephemeris 2.02 introduces new functions for the calculation of Delta T and ayanamsha: swe deltat ex(),

swe\_get\_ayanamsa\_ex\_ut(), and

swe\_get\_ayanamsa\_ex()

(The latter is independent of Delta T, however some ayanamshas like True Chitrapaksha depend on a precise fixed star calculation, which requires a solar ephemeris for annual aberration. Therefore, an ephemeris flag is required.)

Of course, the old functions swe\_deltat(), swe\_get\_ayanamsa(), and swe\_get\_ayanamsa\_ut() are still supported and work without any problems as long as the user uses only one ephemeris flag and calls the function swe\_set\_ephe\_path() (as well swe\_set\_jpl\_file() if using SEFLG\_JPLEPH) before calculating Delta T and planetary positions. Nevertheless, it is recommended to use the new functions swe\_deltat\_ex(), swe\_get\_ayanamsa\_ex(), and swe\_get\_ayanamsa\_ex\_ut() in future projects.

Also, please note that if you calculate planets using swe\_calc\_ut(), and stars using swe\_fixstar\_ut(), you usually need not worry about Delta T and can avoid any such complications.

## 28.16. Changes from version 2.00 to 2.01

Many thanks to those who reported bugs or made valuable suggestions. And I apologize if I forgot to mention some name.

Note: Still unsolved is the problem with the lunar node with SEFLG\_SWIEPH, discovered recently by Mihai (I don't know his full name).

https://groups.yahoo.com/neo/groups/swisseph/conversations/topics/4829?reverse=1

This problem, which has existed "forever", is tricky and will take more time to solve.

Improvements and updates:

• Lunar tidal acceleration for DE431 was updated to -25.8 arcsec/cty^2.

IPN Progress Report 42-196, February 15, 2014, p. 15: W.M. Folkner & alii, "The Planetary and Lunar Ephemerides DE430 and DE431".

- leap seconds of 2012 and 2015 added. (Note, users can add future leap seconds themselves in file seleapsec.txt.
- New values for Delta T until 2015, updated estimations for coming years.
- #define NO\_JPL was removed
- True Pushya paksha ayanamsha added, according to PVR Narasimha Rao.

Fixes for bugs introduced with major release 2.0:

• Topocentric speed of planets was buggy after 2050 and before 1850, which was particularly obvious with slow planets like Neptune or Pluto. (Thanks to Igor "TomCat" Germanenko for pointing out this bug.)

This was caused by the new (since 2.0) long-term algorithm for Sidereal Time, which interfered with the function swe\_calc().

- Topocentric positions of the \*Moon\* after 2050 and before 1850 had an error of a few arc seconds, due to the same problem. With the Sun and the planets, the error was < 0.01 arcsec.
- Another small bug with topocentric positions was fixed that had existed since the first release of topocentric calculations, resulting in very small changes in position for the whole time range of the ephemeris.

Errors due to this bug were < 0.3 arcsec for the Moon and < 0.001" for other objects.

- A small bug in the new long-term algorithm for Sidereal Time, which is used before 1850 and after 2050, was fixed. The error due to this bug was < 0.1 degree for the whole ephemeris time range.
- Since Version 2.0, swe\_set\_tid\_acc() did not work properly anymore, as a result of the new mechanism that chooses tidal acceleration depending on ephemeris. However, this function is not really needed anymore.
- Sidereal modes SE\_SIDBIT\_ECL\_T0, SE\_SIDBIT\_SSY\_PLANE did not work correctly anymore with ayanamshas other than Fagan/Bradley.
- Ephemeris time range was corrected for a few objects:

Chiron ephemeris range defined as 675 AD to 4650 AD.

Pholus ephemeris range defined as -2958 (2959 BC) to 7309 AD.

Time range of interpolated lunar apside defined as -3000 (3001 BC) to 3000 AD.

• Suggestion by Thomas Mack, concerning 32-bit systems:

swephprg.doc ~ 88 ~

#### "... #define FILE OFFSET BITS 64

has to appear before(!) including the standard libraries. ... You then can compile even on 32 bit systems without any need for work arounds."

Fixes for other bugs (all very old):

- Function swe\_lun\_eclipse\_when\_loc(): From now on, an eclipse is considered locally visible if the whole lunar disk is above the local geometric horizon. In former versions, the function has returned incorrect data if the eclipse ended after the rising of the upper and the rising of the lower limb of the moon or if it began between the setting of the lower and the setting of the upper limb of the moon.
- The same applies for the function swe\_sol\_eclipse\_when\_loc(), which had a similar problem.
- Some solar and lunar eclipses were missing after the year 3000 CE.

The following functions were affected:

swe\_lun\_eclipse\_when(), swe\_sol\_eclipse\_when\_glob(), swe\_sol\_eclipse\_when\_loc().

There was no such problem with the remote past, only with the remote future.

- Functions swe\_lunar\_occult\_when\_glob() and swe\_lunar\_occult\_when\_loc() were improved. A better handling of rare
  or impossible events was implemented, so that infinite loops are avoided. For usage of the function, see example in
  swetest.c and programmers docu. The flag SE\_ECL\_ONE\_TRY must be used, and the return value checked, unless you
  are really sure that events do occur.
- swe\_nod\_aps() now understands iflag & SEFLG\_RADIANS
- In swetest, are rounding bug in degrees, minutes, seconds fixed.

180.0000000000000 could have been printed as "179°59'59.1000".

## 28.17. Changes from version 1.80 to 2.00

This is a major release which makes the Swiss Ephemeris fully compatible with JPL Ephemeris DE430/DE431.

A considerable number of functions were updated. That should not be a problem for existing applications. However, the following notes must be made:

- 1. New ephemeris files sepl\*.se1 and semo\*.se1 were created from DE431, covering the time range from 11 Aug. -12999 Jul. (= 4 May -12999 Greg.) to 7 Jan. 16800. For consistent ephemerides, users are advised to use either old sepl\* and semo\* files (based on DE406) or new files (based on DE431) but not mix old and new ones together. The internal handling of old and new files is not 100% identical (because of 3. below).
- 2. Because the time range of DE431 is a lot greater than that of DE406, better algorithms had to be implemented for objects not contained in JPL ephemerides (mean lunar node and apogee). Also, sidereal time and the equation of time had to be updated in order to give sensible results for the whole time range. The results may slightly deviate from former versions of the Swiss Ephemeris, even for epochs inside the time range of the old ephemeris.
- 3. Until version 1.80, the Swiss Ephemeris ignored the fact that the different JPL ephemerides have a different inherent value of the tidal acceleration of the Moon. Calculations of Delta T must be adjusted to this value in order to get best results for the remote past, especially for ancient observations of the Moon and eclipses. Version 2.0 might result in slightly different values for Delta T when compared with older versions of the Swiss Ephemeris. The correct tidal acceleration is automatically set in the functions swe\_set\_ephe\_path() and swe\_set\_jpl\_file(), depending on the available lunar ephemeris. It can also be set using the function swe\_set\_tid\_acc(). Users who work with different ephemerides at the same time, must be aware of this issue. The default value is that of DE430.

New functionality and improvements:

- Former versions of the Swiss Ephemeris were able to exactly reproduce ephemerides of the Astronomical Almanac.
  The new version also supports apparent position as given by the JPL Horizons web interface
  (http://ssd.jpl.nasa.gov/horizons.cgi). Please read the chapter 2.4.5.i in this file above.
- swe\_sidtime() was improved so that it give sensible results for the whole time range of DE431.
- swe\_time\_equ() was improved so that it give sensible results for the whole time range of DE431.
- New functions swe\_Imt\_to\_lat() and swe\_lat\_to\_Imt() were added. They convert local mean time into local apparent time and reverse.
- New function swe\_lun\_eclipse\_when\_loc() provides lunar eclipses that are observable at a given geographic position.
- New ayanamsha SE\_SID\_TRUE\_CITRA (= 27, "true chitrapaksha ayanamsha"). The star Spica is always exactly at 180°.

swephprg.doc ~89 ~

• New ayanamsha SE\_SIDM\_TRUE\_REVATI (= 28), with the star Revati (zeta Piscium) always exactly at 0°. Bug fixes:

- swetest.c, line 556: geopos[10], array size was too small in former versions
- swetest.c, option -t[time] was buggy
- a minor bugfix in swe\_heliacal\_ut(): in some cases, the morning last of the Moon was not found if visibility was bad and the geographic latitude was beyond 50N/S.
- unused function swi\_str\_concat() was removed.

## 28.18. Changes from version 1.79 to 1.80

- Security update: improved some places in code where buffer overflow could occur (thanks to Paul Elliott)
- APC house system
- New function swe\_house\_name(), returns name of house method
- Two new ayanamshas: Suryasiddhanta Revati (359'50 polar longitude) and Citra (180° polar longitude)
- Bug fix in swehel.c, handling of age of observer (thanks to Victor Reijs).
- Bug fix in swe\_lun\_occult\_when\_loc(): correct handling of starting date (thanks to Olivier Beltrami)

## 28.19. Changes from version 1.78 to 1.79

- Improved precision in eclipse calculations: 2<sup>nd</sup> and 3<sup>rd</sup> contact with solar eclipses, penumbral and partial phases with lunar eclipses.
- Bug fix in function swe\_sol\_eclipse\_when\_loc().If the local maximum eclipse occurs at sunset or sunrise, tret[0] now
  gives the moment when the lower limb of the Sun touches the horizon. This was not correctly implemented in former
  versions
- Several changes to C code that had caused compiler warnings (as proposed by Torsten Förtsch).
- Bug fix in Perl functions swe\_house() etc. These functions had crashed with a segmentation violation if called with the house parameter 'G'.
- Bug fix in Perl function swe\_utc\_to\_jd(), where gregflag had been read from the 4<sup>th</sup> instead of the 6<sup>th</sup> parameter.
- Bug fix in Perl functions to do with date conversion. The default mechanism for gregflag was buggy.
- For Hindu astrologers, some more ayanamshas were added that are related to Suryasiddhanta and Aryabhata and are of historical interest.

## 28.20. Changes from version 1.77 to 1.78

- precession is now calculated according to Vondrák, Capitaine, and Wallace 2011.
- Delta t for current years updated.
- new function: swe\_rise\_trans\_true\_hor() for risings and settings at a local horizon with known height.
- functions swe\_sol\_eclipse\_when\_loc(), swe\_lun\_occult\_when\_loc(): return values tret[5] and tret[6] (sunrise and sunset times) added, which had been 0 so far.
- function swe\_lun\_eclipse\_how(): return values attr[4-6] added (azimuth and apparent and true altitude of moon).
- **Attention** with swe\_sol\_eclipse\_how(): return value attr[4] is azimuth, now measured from south, in agreement with the function swe\_azalt() and swe\_azalt\_rev().
- minor bug fix in swe\_rise\_trans(): twilight calculation returned invalid times at high geographic latitudes.
- minor bug fix: when calling swe\_calc() 1. with SEFLG\_MOSEPH, 2. with SEFLG\_SWIEPH, 3. again with SEFLG\_MOSEPH, the result of 1. and 3. were slightly different. Now they agree.
- minor bug fix in swe\_houses(): With house methods H (Horizon), X (Meridian), M (Morinus), and geographic latitudes beyond the polar circle, the ascendant was wrong at times. The ascendant always has to be on the eastern part of the horizon.

swephprg.doc ~90 ~

## 28.21. Changes from version 1.76 to 1.77

- Delta T:
- Current values were updated.
- File sedeltat.txt understands doubles.
- For the period before 1633, the new formulae by Espenak and Meeus (2006) are used. These formulae were derived from Morrison & Stephenson (2004), as used by the Swiss Ephemeris until version 1.76.02.
- The tidal acceleration of the moon contained in LE405/6 was corrected according to Chapront/Chapront-Touzé/Francou A&A 387 (2002), p. 705.

#### Fixed stars:

- There was an error in the handling of the proper motion in RA. The values given in fixstars.cat, which are taken from the Simbad database (Hipparcos), are referred to a great circle and include a factor of cos(d0).
- There is a new fixed stars file sefstars.txt. The parameters are now identical to those in the Simbad database, which makes it much easier to add new star data to the file. If the program function swe\_fixstar() does not find sefstars.txt, it will try the old fixed stars file fixstars.cat and will handle it correctly.
- Fixed stars data were updated, some errors corrected.
- Search string for a star ignores white spaces.

#### Other changes:

- New function swe\_utc\_time\_zone(), converts local time to UTC and UTC to local time. Note, the function has no knowledge about time zones. The Swiss Ephemeris still does not provide the time zone for a given place and time.
- swecl.c: swe\_rise\_trans() has two new minor features: SE\_BIT\_FIXED\_DISC\_SIZE and SE\_BIT\_DISC\_BOTTOM (thanks to Olivier Beltrami)
- minor bug fix in swemmoon.c, Moshier's lunar ephemeris (thanks to Bhanu Pinnamaneni)
- solar and lunar eclipse functions provide additional data:
   attr[8] magnitude, attr[9] saros series number, attr[10] saros series member number

#### 28.22. Changes from version 1.75 to 1.76

#### **New features:**

- Functions for the calculation of heliacal risings and related phenomena, s. chap. 6.15-6.17.
- Functions for conversion between UTC and JD (TT/UT1), s. chap. 7.2 and 7.3.
- File sedeltat.txt allows the user to update Delta T himself regularly, s. chap. 8.3
- Function swe\_rise\_trans(): twilight calculations (civil, nautical, and astronomical) added
- Function swe\_version() returns version number of Swiss Ephemeris.
- Swiss Ephemeris for Perl programmers using XSUB

#### Other updates:

Delta T updated (-2009).

#### Minor bug fixes:

- swe\_house\_pos(): minor bug with Alcabitius houses fixed
- swe\_sol\_eclipse\_when\_glob(): totality times for eclipses jd2456776 and jd2879654 fixed (tret[4], tret[5])

#### 28.23. Changes from version 1.74 to version 1.75

- The Swiss Ephemeris is now able to read ephemeris files of JPL ephemerides DE200 DE421. If JPL will not change the file structure in future releases, the Swiss Ephemeris will be able to read them, as well.
- Function swe\_fixstar() (and swe\_fixstar\_ut()) was made slightly more efficient.
- Function swe\_gauquelin\_sector() was extended.
- Minor bug fixes.

swephprg.doc ~91 ~

### 28.24. Changes from version 1.73 to version 1.74

The Swiss Ephemeris is made available under a dual licensing system:

- a) GNU public license version 2 or later;
- b) Swiss Ephemeris Professional License.

For more details, see at the beginning of this file and at the beginning of every source code file.

Minor bug fixes:

- Bug in swe\_fixstars\_mag() fixed.
- Bug in swe\_nod\_aps() fixed. With retrograde asteroids (20461 Dioretsa, 65407 2002RP120), the calculation of perihelion and aphelion was not correct.
- The ephemeris of asteroid 65407 2002RP120 was updated. It had been wrong before 17 June 2008.

#### 28.25. Changes from version 1.72 to version 1.73

#### **New features:**

- Whole Sign houses implemented (W)
- swe\_house\_pos() now also handles Alcabitius house method
- function swe\_fixstars\_mag() provides fixed stars magnitudes

#### 28.26. Changes from version 1.71 to version 1.72

- Delta T values for recent years were updated
- Delta T calculation before 1600 was updated to Morrison/Stephenson 2004...
- New function swe\_refrac\_extended(), in cooperation with archeoastronomer Victor Reijs.

This function allows correct calculation of refraction for altitudes above sea > 0, where the ideal horizon and planets that are visible may have a negative height.

Minor bugs in swe\_lun\_occult\_when\_glob() and swe\_lun\_eclipse\_how() were fixed.

## 28.27. Changes from version 1.70.03 to version 1.71

In September 2006, Pluto was introduced to the minor planet catalogue and given the catalogue number 134340.

The numerical integrator we use to generate minor planet ephemerides would crash with 134340 Pluto, because Pluto is one of those planets whose gravitational perturbations are used for the numerical integration. Instead of fixing the numerical integrator for this special case, we changed the Swiss Ephemeris functions in such a way that they treat minor planet 134340 Pluto (ipl=SE\_AST\_OFFSET+134340) as our main body Pluto (ipl=SE\_PLUTO=9). This also results in a slightly better precision for 134340 Pluto.

Swiss Ephemeris versions prior to 1.71 are not able to do any calculations for minor planet number 134340.

#### 28.28. Changes from version 1.70.02 to version 1.70.03

Bug fixed (in swecl.c: swi\_bias()): This bug sometimes resulted in a crash, if the DLL was used and the SEFLG\_SPEED was not set. It seems that the error happened only with the DLL and did not appear, when the Swiss Ephemeris C code was directly linked to the application.

Code to do with (#define NO\_MOSHIER) was removed.

#### 28.29. Changes from version 1.70.01 to version 1.70.02

Bug fixed in speed calculation for interpolated lunar apsides. With ephemeris positions close to 0 Aries, speed calculations were completely wrong. E.g. swetest -pc -bj3670817.276275689 (speed = 1448042°!)

Thanks, once more, to Thomas Mack, for testing the software so well.

### 28.30. Changes from version 1.70.00 to version 1.70.01

Bug fixed in speed calculation for interpolated lunar apsides. Bug could result in program crashes if the speed flag was set.

#### 28.31. Changes from version 1.67 to version 1.70

#### Update of algorithms to IAU standard recommendations:

All relevant IAU resolutions up to 2005 have been implemented. These include:

- the "frame bias" rotation from the JPL reference system ICRS to J2000. The correction of position ~= 0.0068 arc sec in right ascension.
- the precession model P03 (Capitaine/Wallace/Chapront 2003). The correction in longitude is smaller than 1 arc second from 1000 B.C. on.
- the nutation model IAU2000B (can be switched to IAU2000A)
- corrections to epsilon
- · corrections to sidereal time
- fixed stars input data can be "J2000" or "ICRS"
- fixed stars conversion FK5 -> J2000, where required
- fixed stars data file was updated with newer data
- constants in sweph.h updated

For more info, see the documentation swisseph.doc, chapters 2.1.2.1-3.

#### **New features:**

• Ephemerides of "interpolated lunar apogee and perigee", as published by Dieter Koch in 2000 (swetest -pcg). For more info, see the documentation swisseph.doc, chapter 2.2.4.

House system according to Bogdan Krusinski (character 'U').

For more info, see the documentation swisseph.doc, chapter 6.1.13.

Bug fixes:

Calculation of magnitude was wrong with asteroid numbers < 10000 (10-nov-05)</li>

### 28.32. Changes from version 1.66 to version 1.67

Delta-T updated with new measured values for the years 2003 and 2004, and better estimates for 2005 and 2006. Bug fixed #define SE\_NFICT\_ELEM 15

#### 28.33. Changes from version 1.65 to version 1.66

#### **New features:**

House system according to Morinus (system 'M').

#### 28.34. Changes from version 1.64.01 to version 1.65.00

'long' variables were changed to 'INT32' for 64-bit compilers.

#### 28.35. Changes from version 1.64 to version 1.64.01

• Bug fixed in swe\_fixstar(). Declinations between -1° and 0° were wrongly taken as positive.

Thanks to John Smith, Serbia, who found this bug.

Several minor bug fixes and cosmetic code improvements suggested by Thomas Mack, Germany.

swetest.c: options -po and -pn work now.

Sweph.c: speed of mean node and mean lunar apogee were wrong in rare cases, near 0 Aries.

swephprg.doc ~ 93 ~

### 28.36. Changes from version 1.63 to version 1.64

#### New features:

- 1. Gauquelin sectors:
- swe\_houses() etc. can be called with house system character 'G' to calculate Gauquelin sector boundaries.
- swe\_house\_pos() can be called with house system 'G' to calculate sector positions of planets.
- swe\_gauquelin\_sector() is new and calculates Gauquelin sector positions with three methods: without ecl. latitude, with ecl. latitude, from rising and setting.
- 2. Waldemath Black Moon elements have been added in seorbel.txt (with thanks to Graham Dawson).
- 3. Occultations of the planets and fixed stars by the moon
- swe\_lun\_occult\_when\_loc() calculates occultations for a given geographic location
- swe\_lun\_occult\_when\_glob() calculates occultations globally
- 4. Minor bug fixes in swe\_fixstar() (Cartesian coordinates), solar eclipse functions, swe\_rise\_trans()
- 5. sweclips.c integrated into swetest.c. Swetest now also calculates eclipses, occultations, risings and settings.
- 6. new Delta T algorithms

## 28.37. Changes from version 1.62 to version 1.63

#### **New features:**

The option –house was added to swetest.c so that swetest.exe can now be used to compute complete horoscopes in textual mode.

Bug fix: a minor bug in function swe\_co\_trans was fixed. It never had an effect.

## 28.38. Changes from version 1.61.03 to version 1.62

#### **New features:**

- 1. Elements for hypothetical bodies that move around the Earth (e.g. Selena/White Moon) can be added to the file seorbel.txt.
- 2. The software will be able to read asteroid files > 55535.

#### Bug fixes:

- 1. error in geocentric planetary descending nodes fixed
- 2. swe\_calc() now allows hypothetical planets beyond SE\_FICT\_OFFSET + 15
- 3. position of hypothetical planets slightly corrected (< 0.01 arc second)

#### 28.39. Changes from version 1.61 to 1.61.01

#### **New features:**

1. swe\_houses and swe\_houses\_armc now supports the Alcabitus house system. The function swe\_house\_pos() does not yet, because we wanted to release quickly on user request.

## 28.40. Changes from version 1.60 to 1.61

#### **New features:**

- 1. Function swe\_rise\_trans(): Risings and settings also for disc center and without refraction
- 2. "topocentric" house system added to swe\_houses() and other house-related functions
- 3. Hypothetical planets (seorbel.txt), orbital elements with t terms are possible now (e.g. for Vulcan according to L.H. Weston)

swephprg.doc ~94 ~

## 28.41. Changes from version 1.51 to 1.60

#### New features:

- 1. Universal time functions swe calc ut(), swe fixstar ut(), etc.
- 2. Planetary nodes, perihelia, aphelia, focal points.
- 3. Risings, settings, and meridian transits of the Moon, planets, asteroids, and stars.
- 4. Horizontal coordinates (azimuth and altitude).
- 5. Refraction.
- 6. User-definable orbital elements.
- 7. Asteroid names can be updated by user.
- 8. Hitherto missing "Personal Sensitive Points" according to M. Munkasey.

#### Minor bug fixes:

- **Astrometric lunar positions** (not relevant for astrology; swe\_calc(tjd, SE\_MOON, SEFLG\_NOABERR)) had a maximum error of about 20 arc sec).
- **Topocentric lunar positions** (not relevant for common astrology): the ellipsoid shape of the Earth was not correctly implemented. This resulted in an error of 2 3 arc seconds. The new precision is 0.2 0.3 arc seconds, corresponding to about 500 m in geographic location. This is also the precision that Nasa's Horizon system provides for the topocentric moon. The planets are much better, of course.
- **Solar eclipse functions**: The correction of the topocentric moon and another small bug fix lead to slightly different results of the solar eclipse functions. The improvement is within a few time seconds.

## 28.42. Changes from version 1.50 to 1.51

#### Minor bug fixes:

- J2000 coordinates for the lunar node and osculating apogee corrected. This bug did not affect ordinary computations like ecliptical or equatorial positions.
- minor bugs in swetest.c corrected
- sweclips.exe recompiled
- · trace DLLs recompiled
- some VB5 declarations corrected

## 28.43. Changes from version 1.40 to 1.50

New: SIDEREAL planetary and house position.

The fixed star file fixstars.cat has been improved and enlarged by Valentin Abramov, Tartu, Estonia.

Stars have been ordered by constellation. Many names and alternative spellings have been added.

Minor bug fix in solar eclipse functions, sometimes relevant in border-line cases annular/total, partial/total.

J2000 coordinates for the lunar nodes were redefined: In versions before 1.50, the J2000 lunar nodes were the intersection points of the lunar orbit with the ecliptic of 2000. From 1.50 on, they are defined as the intersection points with the ecliptic of date, referred to the coordinate system of the ecliptic of J2000.

## 28.44. Changes from version 1.31 to 1.40

New: Function for several planetary phenomena added

Bug fix in swe\_sol\_ecl\_when\_glob(). The time for maximum eclipse at local apparent noon (tret[1]) was sometimes wrong. When called from VB5, the program crashed.

## 28.45. Changes from version 1.30 to 1.31

New: Eclipse functions added.

Minor bug fix: with previous versions, the function swe\_get\_planet\_name() got the name wrong, if it was an asteroid name and consisted of two or more words (e.g. Van Gogh)

## 28.46. Changes from version 1.27 to 1.30

The time range of the Swiss Ephemeris has been extended by numerical integration. The Swiss Ephemeris now covers the period **2 Jan 5401 BC** to **31 Dec 5399 AD**. To use the extended time range, the appropriate ephemeris files must be downloaded.

In the JPL mode and the Moshier mode the time range remains unchanged at 3000 BC to 3000 AD.

#### **IMPORTANT**

Chiron's ephemeris is now restricted to the time range 650 AD - 4650 AD; for explanations, see swisseph.doc.

Outside this time range, Swiss Ephemeris returns an error code and a position value 0. You must handle this situation in your application. There is a similar restriction with Pholus (as with some other asteroids).

## 28.47. Changes from version 1.26 to 1.27

The environment variable SE\_EPHE\_PATH is now always overriding the call to swe\_set\_ephe\_path() if it is set and contains a value.

Both the environment variable and the function argument can now contain a list of directory names where the ephemeris files are looked for. Before this release, they could contain only a single directory name.

## 28.48. Changes from version 1.25 to 1.26

- The asteroid subdirectory ephe/asteroid has been split into directories ast0, ast1,... with 1000 asteroid files per directory.
- source code is included with the distribution under the new licensing model
- the Placalc compatibility API (swepcalc.h) is now documented
- There is a new function to compute the equation of time swe\_time\_equ().
- Improvements of ephemerides:
- ATTENTION: Ephemeris of **16 Psyche** has been wrong so far! By a mysterious mistake it has been identical to 3 Juno.
- Ephemerides of Ceres, Pallas, Vesta, Juno, Chiron and Pholus have been reintegrated, with more recent orbital elements and parameters (e.g. asteroid masses) that are more appropriate to Bowells database of minor planets elements. The differences are small, though.
- Note that the <u>CHIRON</u> ephemeris should not be used before **700 A.D.**
- Minor bug fix in computation of topocentric planet positions. Nutation has not been correctly considered in observer's position. This has led to an error of 1 milliarcsec with the planets and 0.1" with the moon.
- We have inactivated the coordinate transformation from **IERS** to **FK5**, because there is still no generally accepted algorithm. This results in a difference of a few milliarcsec from former releases.

## 28.49. Changes from version 1.22 to 1.23

- The topocentric flag now also works with the fixed stars. (The effect of diurnal aberration is a few 0.1 arc second.)
- Bug fix: The return position of swe\_cotrans\_sp() has been 0, when the input distance was 0.
- About 140 asteroids are on the CD.

#### 28.50. Changes from version 1.21 to 1.22

- Asteroid ephemerides have been moved to the ephe\asteroid.
- The DLL has been modified in such a way that it can find them there.
- All asteroids with catalogue number below 90 are on the CD and a few additional ones.

swephprg.doc ~ 96 ~

## 28.51. Changes from version 1.20 to 1.21

Sample program and function declarations for Delphi 1.0 added.

### 28.52. Changes from version 1.11 to 1.20

#### New:

- A flag bit SEFLG\_TOPOCTR allows to compute topocentric planet positions. Before calling swe\_calc(), call swe\_set\_topo.
- <u>swe house pos</u> for computation of the house position of a given planet. See description in SWISSEPH.DOC, Chapter 3.1 "Geocentric and topocentric positions". A bug has been fixed that has sometimes turned up, when the JPL ephemeris was closed. (An error in memory allocation and freeing.)
- Bug fix: swe\_cotrans() did not work in former versions.

#### 28.53. Changes from version 1.10 to 1.11

No bug fix, but two minor improvements:

- A change of the ephemeris bits in parameter **iflag** of function swe\_calc() usually forces an implicit swe\_close() operation. Inside a loop, e.g. for drawing a graphical ephemeris, this can slow down a program. Before this release, two calls with iflag = 0 and iflag = SEFLG\_SWIEPH where considered different, though in fact the same ephemeris is used. Now these two calls are considered identical, and swe\_close() is not performed implicitly. For calls with the pseudo-planet-number ipl = SE\_ECL\_NUT, whose result does not depend on the chosen ephemeris, the ephemeris bits are ignored completely and swe\_close() is never performed implicitly.
- In former versions, calls of the Moshier ephemeris with speed and without speed flag have returned a very small difference in position (0.01 arc second). The reason was that, for precise speed, swe\_calc() had to do an additional iteration in the light-time calculation. The two calls now return identical position data.

## 28.54. Changes from version 1.04 to 1.10

- A bug has been fixed that sometimes occurred in swe\_calc() when the user changed iflag between calls, e.g. the speed flag. The first call for a planet which had been previously computed for the same time, but a different iflag, could return incorrect results, if Sun, Moon or Earth had been computed for a different time in between these two calls.
- More asteroids have been added in this release.

## 28.55. Changes from Version 1.03 to 1.04

- A bug has been fixed that has sometimes lead to a floating point exception when the speed flag was not specified and an unusual sequence of planets was called.
- Additional asteroid files have been included.

**Attention**: Use these files only with the new DLL. Previous versions cannot deal with more than one additional asteroid besides the main asteroids. This error did not appear so far, because only 433 Eros was on our CD-ROM.

## 28.56. Changes from Version 1.02 to 1.03

- swe\_fixstar() has a better implementation for the search of a specific star. If a number is given, the non-comment lines in the file fixstars.cat are now counted from 1; they were counted from zero in earlier releases.
- swe\_fixstar() now also computes heliocentric and barycentric fixed stars positions. Former versions Swiss Ephemeris always returned geocentric positions, even if the heliocentric or the barycentric flag bit was set.
- The Galactic Center has been included in fixstars.cat.
- Two small bugs were fixed in the implementation of the barycentric Sun and planets. Under unusual conditions, e.g.
  if the caller switched from JPL to Swiss Ephemeris or vice-versa, an error of an arc second appeared with the
  barycentric sun and 0.001 arc sec with the barycentric planets. However, this did not touch normal geocentric

swephprg.doc ~ 97 ~

computations.

Some VB declarations in swedecl.txt contained errors and have been fixed. The VB sample has been extended to show fixed star and house calculation. This fix is only in 1.03 releases from 29-oct-97 or later, not in the two 1.03 CDROMs we burned on 28-oct-97.

#### 28.57. Changes from Version 1.01 to 1.02

- The function swe houses() has been changed.
- A new function swe\_houses\_armc() has been added which can be used when a sidereal time (armc) is given but no actual date is known, e.g. for Composite charts.
- The body numbers of the hypothetical bodies have been changed.
- The development environment for the DLL and the sample programs have been changed from Watcom 10.5 to Microsoft Visual C++ (5.0 and 1.5). This was necessary because the Watcom compiler created LIB files which were not compatible with Microsoft C. The LIB files created by Visual C however are compatible with Watcom.

#### 28.58. Changes from Version 1.00 to 1.01

#### 28.58.1. Sidereal time

The computation of the sidereal time is now much easier. The obliquity and nutation are now computed inside the function. The structure of the function swe sidtime() has been changed as follows:

```
/* sidereal time */
```

double swe\_sidtime(double tjd\_ut); /\* Julian day number, UT \*/

The old functions swe\_sidtime0() has been kept for backward compatibility.

#### 28.58.2. Houses

The calculation of houses has been simplified as well. Moreover, the Vertex has been added.

The version 1.01 structure of swe houses() is:

```
int swe_houses(
```

double \*cusps);

```
/* Julian day number, UT */
double tjd_ut,
                         /* geographic latitude, in degrees */
double geolat,
double geolon,
                         /* geographic longitude, in degrees */
                         /* house method, one of the letters PKRCAV */
char hsys,
                         /* address for ascendant */
double *asc,
double *mc,
                         /* address for mc */
                         /* address for armc */
double *armc.
double *vertex,
                         /* address for vertex */
                         /* address for 13 doubles: 1 empty + 12 houses */
```

**Note** also, that the indices of the cusps have changed:

```
cusp[0] = 0
                          (before: cusp[0] = house 1)
cusp[1] = house 1
                          (before: cusp[1] = house 2)
cusp[2] = house 2
                          (etc.)
etc.
```

#### 28.58.3. Ecliptic obliquity and nutation

The new pseudo-body SE\_ECL\_NUT replaces the two separate pseudo-bodies SE\_ECLIPTIC and SE\_NUTATION in the function swe\_calc().

swephprg.doc ~ 98 ~ Swiss Ephemeris 2.08 What is missing?

## 29. What is missing?

There are some important limits in regard to what you can expect from an ephemeris module. We do not tell you:

- how to draw a chart;
- which glyphs to use;
- when a planet is stationary;
- how to compute universal time from local time, i.e. what timezone a place is located in;
- how to compute progressions, solar returns, composite charts, transit times and a lot more;
- what the different calendars (Julian, Gregorian ...) mean and when they apply.

Swiss Ephemeris 2.08

	Function	Description
1	swe_azalt	computes the horizontal coordinates (azimuth and altitude)
2	swe_azalt_rev	computes either ecliptical or equatorial coordinates from azimuth and true altitude
3	swe_calc	computes the positions of planets, asteroids, lunar nodes and apogees
4	swe_calc_ut	modified version of swe_calc
5	swe_close	releases most resources used by the Swiss Ephemeris
6	swe_cotrans	coordinate transformation, from ecliptic to equator or vice-versa
7	swe_cotrans_sp	coordinate transformation of position and speed, from ecliptic to equator or vice-versa
8	swe_date_conversion	computes a Julian day from year, month, day, time and checks whether a date is legal
9	swe_degnorm	normalization of any degree number to the range 0 360
10	swe_deltat	computes the difference between Universal Time (UT, GMT) and Ephemeris time
11	swe_fixstar	computes fixed stars
12	swe_fixstar_ut	modified version of swe_fixstar
13	swe_get_ayanamsa	computes the ayanamsha
14	swe_get_ayanamsa_ut	modified version of swe_get_ayanamsa
15	swe_get_planet_name	finds a planetary or asteroid name by given number
16	swe_get_tid_acc	gets the tidal acceleration
17	swe_heliacal_ut	compute heliacal risings etc. of a planet or star
18	swe_house_pos	compute the house position of a given body for a given ARMC
19	swe_houses	calculates houses for a given date and geographic position
20	swe_houses_armc	computes houses from ARMC (e.g. with the composite horoscope which has no date)
21	swe_houses_ex	the same as swe_houses(). Has a parameter, which can be used, if sidereal house positions are wanted
22	swe_jdet_to_utc	converts JD (ET/TT) to UTC
23	swe_jdut1_to_utc	converts JD (UT1) to UTC
24	swe_julday	conversion from day, month, year, time to Julian date
25	swe_lat_to_lmt	converts local apparent time (LAT) to local mean time (LMT)
26	swe_lmt_to_lat	converts local mean time (LMT) to local apparent time (LAT)
27	swe_lun_eclipse_how	computes the attributes of a lunar eclipse at a given time
28	swe_lun_eclipse_when	finds the next lunar eclipse
29	swe_lun_eclipse_when_loc	finds the next lunar eclipse observable from a geographic location
30	swe_nod_aps	computes planetary nodes and apsides: perihelia, aphelia, second focal points of the orbital ellipses
31	swe_nod_aps_ut	modified version of swe_nod_aps
32	swe_pheno	computes phase, phase angle, elongation, apparent diameter, apparent magnitude
33	swe_pheno_ut	modified version of swe_pheno
34	swe_refrac	the true/apparent altitude conversion
35	swe_refrac_extended	the true/apparent altitude conversion
36	swe_revjul	conversion from Julian date to day, month, year, time
37	swe_rise_trans	computes the times of rising, setting and meridian transits
38	swe_rise_trans_true_hor	computes the times of rising, setting and meridian transits relative to true horizon

swephprg.doc ~ 101 ~

Swiss Ephemeris 2.08

39	swe_set_ephe_path	set application's own ephemeris path
40	swe_set_jpl_file	sets JPL ephemeris directory path
41	swe_set_sid_mode	specifies the sidereal modes
42	swe_set_tid_acc	sets tidal acceleration used in swe_deltat()
43	swe_set_topo	sets what geographic position is to be used before topocentric planet positions for a certain birth place can be computed
44	swe_sidtime	returns sidereal time on Julian day
45	swe_sidtime0	returns sidereal time on Julian day, obliquity and nutation
46	swe_sol_eclipse_how	calculates the solar eclipse attributes for a given geographic position and time
47	swe_sol_eclipse_when_glob	finds the next solar eclipse globally
48	swe_sol_eclipse_when_loc	finds the next solar eclipse for a given geographic position
49	swe_sol_eclipse_where	finds out the geographic position where an eclipse is central or maximal
50	swe_time_equ	returns the difference between local apparent and local mean time
51	swe_utc_time_zone	converts UTC int time zone time
52	swe_version	returns the version of the Swiss Ephemeris
53	swe_vis_limit_mag	calculates the magnitude for an object to be visible

PlaCalc function	Description
swe_csnorm	normalize argument into interval [0DEG360]
swe_cs2degstr	centiseconds -> degrees string
swe_cs2lonlatstr	centiseconds -> longitude or latitude string
swe_cs2timestr	centiseconds -> time string
swe_csroundsec	round second, but at 29.5959 always down
swe_d2l	double to long with rounding, no overflow check
swe_day_of_week	day of week Monday = 0, Sunday = 6
swe_difcs2n	distance in centisecs p1 – p2 normalized to [-180180]
swe_difcsn	distance in centisecs p1 – p2 normalized to [0360]
swe_difdeg2n	distance in degrees
swe_difdegn	distance in degrees
